

SOLUTIONS

CHAPTER 1

Exercise 1.1

(a) Biologists study cells at many levels. The cells are built from organelles such as the mitochondria, ribosomes, and chloroplasts. Organelles are built of macromolecules such as proteins, lipids, nucleic acids, and carbohydrates. These biochemical macromolecules are built simpler molecules such as carbon chains and amino acids. When studying at one of these levels of abstraction, biologists are usually interested in the levels above and below: what the structures at that level are used to build, and how the structures themselves are built.

(b) The fundamental building blocks of chemistry are electrons, protons, and neutrons (physicists are interested in how the protons and neutrons are built). These blocks combine to form atoms. Atoms combine to form molecules. For example, when chemists study molecules, they can abstract away the lower levels of detail so that they can describe the general properties of a molecule such as benzene without having to calculate the motion of the individual electrons in the molecule.

Exercise 1.2

(a) Automobile designers use hierarchy to construct a car from major assemblies such as the engine, body, and suspension. The assemblies are constructed from subassemblies; for example, the engine contains cylinders, fuel injectors, the ignition system, and the drive shaft. Modularity allows components to be swapped without redesigning the rest of the car; for example, the seats can be cloth, leather, or leather with a built in heater depending on the model of the vehicle, so long as they all mount to the body in the same place. Regularity involves the use of interchangeable parts and the sharing of parts between different vehicles; a 65R14 tire can be used on many different cars.

(b) Businesses use hierarchy in their organization chart. An employee reports to a manager, who reports to a general manager who reports to a vice president who reports to the president. Modularity includes well-defined interfaces between divisions. The salesperson who spills a coke in his laptop calls a single number for technical support and does not need to know the detailed organization of the information systems department. Regularity includes the use of standard procedures. Accountants follow a well-defined set of rules to calculate profit and loss so that the finances of each division can be combined to determine the finances of the company and so that the finances of the company can be reported to investors who can make a straightforward comparison with other companies.

Exercise 1.3

Ben can use a hierarchy to design the house. First, he can decide how many bedrooms, bathrooms, kitchens, and other rooms he would like. He can then jump up a level of hierarchy to decide the overall layout and dimensions of the house. At the top-level of the hierarchy, he material he would like to use, what kind of roof, etc. He can then jump to an even lower level of hierarchy to decide the specific layout of each room, where he would like to place the doors, windows, etc. He can use the principle of regularity in planning the framing of the house. By using the same type of material, he can scale the framing depending on the dimensions of each room. He can also use regularity to choose the same (or a small set of) doors and windows for each room. That way, when he places a new door or window he need not redesign the size, material, layout specifications from scratch. This is also an example of modularity: once he has designed the specifications for the windows in one room, for example, he need not re-specify them when he uses the same windows in another room. This will save him both design time and, thus, money. He could also save by buying some items (like windows) in bulk.

Exercise 1.4

An accuracy of ± 50 mV indicates that the signal can be resolved to 100 mV intervals. There are 50 such intervals in the range of 0-5 volts, so the signal represents $\log_2 50 = 5.64$ bits of information.

Exercise 1.5

(a) The hour hand can be resolved to $12 * 4 = 48$ positions, which represents $\log_2 48 = 5.58$ bits of information. (b) Knowing whether it is before or after noon adds one more bit.

Exercise 1.6

Each digit conveys $\log_2 60 = 5.91$ bits of information. $4000_{10} = 1\ 6\ 40_{60}$ (1 in the 3600 column, 6 in the 60's column, and 40 in the 1's column).

Exercise 1.7

$$2^{16} = 65,536 \text{ numbers.}$$

Exercise 1.8

$$2^{32} - 1 = 4,294,967,295$$

Exercise 1.9

$$(a) 2^{16} - 1 = 65535; (b) 2^{15} - 1 = 32767; (c) 2^{15} - 1 = 32767$$

Exercise 1.10

$$(a) 2^{32} - 1 = 4,294,967,295; (b) 2^{31} - 1 = 2,147,483,647; (c) 2^{31} - 1 = 2,147,483,647$$

Exercise 1.11

$$(a) 0; (b) -2^{15} = -32768; (c) -(2^{15} - 1) = -32767$$

Exercise 1.12

$$(a) 0; (b) -2^{31} = -2,147,483,648; (c) -(2^{31} - 1) = -2,147,483,647;$$

Exercise 1.13

$$(a) 10; (b) 54; (c) 240; (d) 2215$$

Exercise 1.14

$$(a) 14; (b) 36; (c) 215; (d) 15,012$$

Exercise 1.15

$$(a) A; (b) 36; (c) F0; (d) 8A7$$

Exercise 1.16

(a) E; (b) 24; (c) D7; (d) 3AA4

Exercise 1.17

(a) 165; (b) 59; (c) 65535; (d) 3489660928

Exercise 1.18

(a) 78; (b) 124; (c) 60,730; (d) 1,077,915, 649

Exercise 1.19

(a) 10100101; (b) 00111011; (c) 1111111111111111;
(d) 11010000000000000000000000000000

Exercise 1.20

(a) 1001110; (b) 1111100; (c) 1110110100111010; (d) 100 0000 0011
1111 1011 0000 0000 0001

Exercise 1.21

(a) -6; (b) -10; (c) 112; (d) -97

Exercise 1.22

(a) -2 ($-8+4+2 = -2$ or magnitude = $0001+1 = 0010$: thus, -2); (b) -29 (-32
 $+2+1 = -29$ or magnitude = $011100+1 = 011101$: thus, -29); (c) 78; (d) -75

Exercise 1.23

(a) -2; (b) -22; (c) 112; (d) -31

Exercise 1.24

(a) -6; (b) -3; (c) 78; (d) -53

Exercise 1.25

(a) 101010; (b) 111111; (c) 11100101; (d) 1101001101

Exercise 1.26

(a) 1110; (b) 110100; (c) 101010011; (d) 1011000111

Exercise 1.27

(a) 2A; (b) 3F; (c) E5; (d) 34D

Exercise 1.28

(a) E; (b) 34; (c) 153; (d) 2C7;

Exercise 1.29

(a) 00101010; (b) 11000001; (c) 01111100; (d) 10000000; (e) overflow

Exercise 1.30

(a) 00011000; (b) 11000101; (c) overflow; (d) overflow; (e) 01111111\

Exercise 1.31

00101010; (b) 10111111; (c) 01111100; (d) overflow; (e) overflow

Exercise 1.32

(a) 00011000; (b) 10111011; (c) overflow; (d) overflow; (e) 01111111

Exercise 1.33

(a) 00000101; (b) 11111010

Exercise 1.34

(a) 00000111; (b) 11111001

Exercise 1.35

(a) 00000101; (b) 00001010

Exercise 1.36

(a) 00000111; (b) 00001001

Exercise 1.37

(a) 52; (b) 77; (c) 345; (d) 1515

Exercise 1.38

(a) 0o16; (b) 0o64; (c) 0o339; (d) 0o1307

Exercise 1.39

(a) 100010_2 , 22_{16} , 34_{10} ; (b) 110011_2 , 33_{16} , 51_{10} ; (c) 010101101_2 , AD_{16} , 173_{10} ; (d) 011000100111_2 , 627_{16} , 1575_{10}

Exercise 1.40

(a) 0b10011; 0x13; 19; (b) 0b100101; 0x25; 37; (c) 0b11111001; 0xF9; 249; (d) 0b10101110000; 0x570; 1392

Exercise 1.41

15 greater than 0, 16 less than 0; 15 greater and 15 less for sign/magnitude

Exercise 1.42

(26-1) are greater than 0; 26 are less than 0. For sign/magnitude numbers, (26-1) are still greater than 0, but (26-1) are less than 0.

Exercise 1.43

4, 8

Exercise 1.44

8

Exercise 1.45

5,760,000

Exercise 1.46

$(5 \times 10^9 \text{ bits/second})(60 \text{ seconds/minute})(1 \text{ byte/8 bits}) = 3.75 \times 10^{10}$
bytes

Exercise 1.47

46.566 gigabytes

Exercise 1.48

2 billion

Exercise 1.49

128 kbits

Exercise 1.50

Exercise 1.51

Exercise 1.52

(a) 1101; (b) 11000 (overflows)

Exercise 1.53

(a) 11011101; (b) 110001000 (overflows)

Exercise 1.54

(a) 11012, no overflow; (b) 10002, no overflow

Exercise 1.55

(a) 11011101; (b) 110001000

Exercise 1.56

- (a) $010000 + 001001 = 011001$;
- (b) $011011 + 011111 = 111010$ (overflow);
- (c) $111100 + 010011 = 001111$;
- (d) $000011 + 100000 = 100011$;
- (e) $110000 + 110111 = 100111$;
- (f) $100101 + 100001 = 000110$ (overflow)

Exercise 1.57

- (a) $000111 + 001101 = 010100$
- (b) $010001 + 011001 = 101010$, overflow
- (c) $100110 + 001000 = 101110$
- (d) $011111 + 110010 = 010001$
- (e) $101101 + 101010 = 010111$, overflow
- (f) $111110 + 100011 = 100001$

Exercise 1.58

(a) 10; (b) 3B; (c) E9; (d) 13C (overflow)

Exercise 1.59

(a) 0x2A; (b) 0x9F; (c) 0xFE; (d) 0x66, overflow

Exercise 1.60

(a) $01001 - 00111 = 00010$; (b) $01100 - 01111 = 11101$; (c) $11010 - 01011 = 01111$; (d) $00100 - 11000 = 01100$

Exercise 1.61

(a) $010010 + 110100 = 000110$; (b) $011110 + 110111 = 010101$; (c) $100100 + 111101 = 100001$; (d) $110000 + 101011 = 011011$, overflow

Exercise 1.62

(a) 3; (b) 01111111; (c) $00000000_2 = -127_{10}$; $11111111_2 = 128_{10}$

Exercise 1.63

Exercise 1.64

(a) 001010001001; (b) 951; (c) 1000101; (d) each 4-bit group represents one decimal digit, so conversion between binary and decimal is easy. BCD can also be used to represent decimal fractions exactly.

Exercise 1.65

- (a) 0011 0111 0001
- (b) 187
- (c) $95 = 1011111$

(d) Addition of BCD numbers doesn't work directly. Also, the representation doesn't maximize the amount of information that can be stored; for example 2 BCD digits requires 8 bits and can store up to 100 values (0-99) - unsigned 8-bit binary can store 28 (256) values.

Exercise 1.66

Three on each hand, so that they count in base six.

Exercise 1.67

Both of them are full of it. $42_{10} = 101010_2$, which has 3 1's in its representation.

Exercise 1.68

Both are right.

Exercise 1.69

```
#include <stdio.h>
```

```
void main(void)
{
    char bin[80];
    int i = 0, dec = 0;

    printf("Enter binary number: ");
    scanf("%s", bin);

    while (bin[i] != 0) {
        if (bin[i] == '0') dec = dec * 2;
        else if (bin[i] == '1') dec = dec * 2 + 1;
        else printf("Bad character %c in the number.\n", bin[i]);
        i = i + 1;
    }
    printf("The decimal equivalent is %d\n", dec);
}
```

Exercise 1.70

```
/* This program works for numbers that don't overflow the
   range of an integer. */

#include <stdio.h>

void main(void)
{
    int b1, b2, digits1 = 0, digits2 = 0;
    char num1[80], num2[80], tmp, c;
    int digit, num = 0, j;

    printf ("Enter base #1: "); scanf("%d", &b1);
    printf ("Enter base #2: "); scanf("%d", &b2);
    printf ("Enter number in base %d ", b1); scanf("%s", num1);

    while (num1[digits1] != 0) {
        c = num1[digits1++];
        if (c >= 'a' && c <= 'z') c = c + 'A' - 'a';
        if (c >= '0' && c <= '9') digit = c - '0';
        else if (c >= 'A' && c <= 'F') digit = c - 'A' + 10;
        else printf("Illegal character %c\n", c);
        if (digit >= b1) printf("Illegal digit %c\n", c);
        num = num * b1 + digit;
    }

    while (num > 0) {
        digit = num % b2;
        num = num / b2;
        num2[digits2++] = digit < 10 ? digit + '0' : digit + 'A' -
10;
    }
    num2[digits2] = 0;

    for (j = 0; j < digits2/2; j++) { // reverse order of digits
        tmp = num2[j];
        num2[j] = num2[digits2-j-1];
        num2[digits2-j-1] = tmp;
    }

    printf("The base %d equivalent is %s\n", b2, num2);
}
```

Exercise 1.77

2^{2^N}

Exercise 1.78

$V_{IL} = 2.5; V_{IH} = 3; V_{OL} = 1.5; V_{OH} = 4; NM_L = 1; NM_H = 1$

Exercise 1.79

No, there is no legal set of logic levels. The slope of the transfer characteristic never is better than -1, so the system never has any gain to compensate for noise.

Exercise 1.80

$V_{IL} = 2; V_{IH} = 4; V_{OL} = 1; V_{OH} = 4.5; NM_L = 1; NM_H = 0.5$

Exercise 1.81

The circuit functions as a buffer with logic levels $V_{IL} = 1.5$; $V_{IH} = 1.8$; $V_{OL} = 1.2$; $V_{OH} = 3.0$. It can receive inputs from LVCMOS and LVTTL gates because their output logic levels are compatible with this gate's input levels. However, it cannot drive LVCMOS or LVTTL gates because the $1.2 V_{OL}$ exceeds the V_{IL} of LVCMOS and LVTTL.

Exercise 1.82

(a) AND gate; (b) $V_{IL} = 1.5$; $V_{IH} = 2.25$; $V_{OL} = 0$; $V_{OH} = 3$

Exercise 1.83

(a) XOR gate; (b) $V_{IL} = 1.25$; $V_{IH} = 2$; $V_{OL} = 0$; $V_{OH} = 3$

Exercise 1.84

Exercise 1.85

1	1	0	0
1	1	1	0

Exercise 1.89

Exercise 1.90

Question 1.1

Question 1.2

4 times. Place 22 coins on one side and 22 on the other. If one side rises, the fake is on that side. Otherwise, the fake is among the 20 remaining. From the group containing the fake, place 8 on one side and 8 on the other. Again, identify which group contains the fake. From that group, place 3 on one side and 3 on the other. Again, identify which group contains the fake. Finally, place 1 coin on each side. Now the fake coin is apparent.

Question 1.3

17 minutes: (1) designer and freshman cross (2 minutes); (2) freshman returns (1 minute); (3) professor and TA cross (10 minutes); (4) designer returns (2 minutes); (5) designer and freshman cross (2 minutes).

CHAPTER 2

Exercise 2.1

(a) $Y = \bar{A}\bar{B} + A\bar{B} + AB$

(b) $Y = \bar{A}\bar{B}\bar{C} + ABC$

(c) $Y = \bar{A}\bar{B}\bar{C} + \bar{A}B\bar{C} + A\bar{B}\bar{C} + A\bar{B}C + ABC$

(d)

$$Y = \bar{A}\bar{B}\bar{C}\bar{D} + \bar{A}\bar{B}\bar{C}D + \bar{A}\bar{B}C\bar{D} + \bar{A}B\bar{C}\bar{D} + \bar{A}B\bar{C}D + \bar{A}BC\bar{D} + \bar{A}BCD$$

(e)

$$Y = \bar{A}\bar{B}\bar{C}\bar{D} + \bar{A}\bar{B}\bar{C}D + \bar{A}\bar{B}C\bar{D} + \bar{A}B\bar{C}\bar{D} + \bar{A}B\bar{C}D + \bar{A}BC\bar{D} + \bar{A}BCD + ABCD$$

Exercise 2.2

(a) $Y = \bar{A}B + A\bar{B} + AB$

(b) $Y = \bar{A}\bar{B}C + \bar{A}B\bar{C} + \bar{A}BC + A\bar{B}\bar{C} + ABC$

(c) $Y = \bar{A}\bar{B}C + AB\bar{C} + ABC$

(d) $Y = \bar{A}\bar{B}\bar{C}\bar{D} + \bar{A}\bar{B}C\bar{D} + \bar{A}B\bar{C}\bar{D} + \bar{A}BC\bar{D} + \bar{A}B\bar{C}D + \bar{A}B\bar{C}\bar{D} + \bar{A}BCD$

(e) $Y = \bar{A}\bar{B}\bar{C}\bar{D} + \bar{A}\bar{B}C\bar{D} + \bar{A}B\bar{C}\bar{D} + \bar{A}BC\bar{D} + \bar{A}B\bar{C}D + \bar{A}B\bar{C}\bar{D} + \bar{A}BCD$

Exercise 2.3

(a) $Y = (A + \bar{B})$

(b)

$$Y = (A + B + \bar{C})(A + \bar{B} + C)(A + \bar{B} + \bar{C})(\bar{A} + B + C)(\bar{A} + B + \bar{C})(\bar{A} + \bar{B} + C)$$

(c) $Y = (A + B + \bar{C})(A + \bar{B} + \bar{C})(\bar{A} + \bar{B} + C)$

(d)

$$Y = (A + \bar{B} + C + D)(A + \bar{B} + C + \bar{D})(A + \bar{B} + \bar{C} + D)(A + \bar{B} + \bar{C} + \bar{D})(\bar{A} + B + C + \bar{D})$$

$$(\bar{A} + B + \bar{C} + \bar{D})(\bar{A} + \bar{B} + C + D)(\bar{A} + \bar{B} + C + \bar{D})(\bar{A} + \bar{B} + \bar{C} + D)$$

(e)

$$Y = (A + B + C + \bar{D})(A + B + \bar{C} + D)(A + \bar{B} + C + D)(A + \bar{B} + \bar{C} + \bar{D})(\bar{A} + B + C + D)$$

$$(\bar{A} + B + \bar{C} + \bar{D})(\bar{A} + \bar{B} + C + D)(\bar{A} + \bar{B} + \bar{C} + D)$$

Exercise 2.4

(a) $Y = A + B$

(b) $Y = (A + B + C)(\bar{A} + B + \bar{C})(\bar{A} + \bar{B} + \bar{C})$

(c) $Y = (A + B + C)(A + \bar{B} + C)(A + \bar{B} + \bar{C})(\bar{A} + B + C)(\bar{A} + B + \bar{C})$

(d)

$$Y = (A + B + C + \bar{D})(A + \bar{B} + C + D)(A + \bar{B} + C + \bar{D})(\bar{A} + B + C + \bar{D})$$

$$(\bar{A} + B + \bar{C} + \bar{D})(\bar{A} + \bar{B} + C + D)(\bar{A} + \bar{B} + C + \bar{D})(\bar{A} + \bar{B} + \bar{C} + D)$$

$$(\bar{A} + \bar{B} + \bar{C} + \bar{D})$$

(e)

$$Y = (A + B + C + D)(A + B + C + \bar{D})(A + B + \bar{C} + D)(A + \bar{B} + C + D)$$

$$(\bar{A} + \bar{B} + \bar{C} + \bar{D})(\bar{A} + \bar{B} + C + D)(\bar{A} + \bar{B} + C + \bar{D})(\bar{A} + \bar{B} + \bar{C} + D)$$

$$(\bar{A} + \bar{B} + \bar{C} + \bar{D})$$

Exercise 2.5

(a) $Y = A + \bar{B}$

(b) $Y = \bar{A}\bar{B}\bar{C} + ABC$

(c) $Y = \bar{A}\bar{C} + A\bar{B} + AC$

(d) $Y = \bar{A}\bar{B} + \bar{B}\bar{D} + ACD$

(e)

$$Y = \bar{A}\bar{B}\bar{C}\bar{D} + \bar{A}\bar{B}CD + \bar{A}B\bar{C}\bar{D} + \bar{A}BC\bar{D} + A\bar{B}\bar{C}\bar{D} + A\bar{B}C\bar{D} + AB\bar{C}\bar{D} + ABCD$$

This can also be expressed as:

$$Y = \overline{(A \oplus B)}\overline{(C \oplus D)} + (A \oplus B)(C \oplus D)$$

Exercise 2.6

(a) $Y = A + B$

(b) $Y = A\bar{C} + \bar{A}C + B\bar{C}$ or $Y = A\bar{C} + \bar{A}C + \bar{A}B$

(c) $Y = AB + \bar{A}\bar{B}C$

(d) $Y = BC + \bar{B}\bar{D}$

(e) $Y = A\bar{B} + \bar{A}BC + \bar{A}CD$ or $Y = A\bar{B} + \bar{A}BC + \bar{B}CD$

Exercise 2.7

(a)

(b)

(c)

(d)

(e)

Exercise 2.8

Exercise 2.9

(a) Same as 2.7(a)

Exercise 2.12

Exercise 2.13

- (a) $Y = AC + \overline{B}C$
 (b) $Y = \overline{A}$
 (c) $Y = \overline{A} + \overline{B}\overline{C} + \overline{B}\overline{D} + BD$

Exercise 2.14

- (a) $Y = \overline{A}B$
 (b) $Y = \overline{A} + \overline{B} + \overline{C} = \overline{ABC}$

$$(c) Y = A(\bar{B} + \bar{C} + \bar{D}) + \bar{B}\bar{C}\bar{D} = \overline{ABCD} + \bar{B}\bar{C}\bar{D}$$

Exercise 2.15

(a)

(b)

(c)

Exercise 2.16

(a)

(b)

(c)

Exercise 2.17

(a) $Y = B + \bar{A}\bar{C}$

(b) $Y = \bar{A}B$

(c) $Y = A + \bar{B}\bar{C} + \bar{D}\bar{E}$

Exercise 2.18

(a) $Y = \bar{B} + C$

(b) $Y = (A + \bar{C})D + B$

(c) $Y = B\bar{D}E + BD(\overline{A \oplus C})$

Exercise 2.19

4 gigarows = 4×2^{30} rows = 2^{32} rows, so the truth table has 32 inputs.

Exercise 2.20

Exercise 2.21

Ben is correct. For example, the following function, shown as a K-map, has two possible minimal sum-of-products expressions. Thus, although $\overline{A}\overline{C}\overline{D}$ and $\overline{B}\overline{C}\overline{D}$ are both prime implicants, the minimal sum-of-products expression does not have both of them.

Exercise 2.22

(a)

B	B • B
0	0
1	1

(b)

B	C	D	$(B \bullet C) + (B \bullet D)$	$B \bullet (C + D)$
0	0	0	0	0
0	0	1	0	0
0	1	0	0	0
0	1	1	0	0
1	0	0	0	0
1	0	1	1	1
1	1	0	1	1
1	1	1	1	1

(c)

B	C	$(B \bullet C) + (B \bullet \bar{C})$
0	0	0
0	1	0
1	0	1
1	1	1

Exercise 2.23

B_2	B_1	B_0	$\overline{B_2 \bullet B_1 \bullet B_0}$	$\overline{B_2} + \overline{B_1} + \overline{B_0}$
0	0	0	1	1
0	0	1	1	1
0	1	0	1	1
0	1	1	1	1
1	0	0	1	1
1	0	1	1	1
1	1	0	1	1
1	1	1	0	0

Exercise 2.24

$$Y = \bar{A}D + \bar{A}\bar{B}C + \bar{A}\bar{C}D + ABCD$$

$$Z = \bar{A}\bar{C}D + BD$$

Exercise 2.25

Exercise 2.26

$$Y = (\bar{A} + \bar{B})(\bar{C} + \bar{D}) + \bar{E}$$

Exercise 2.27

$$Y = ABC + \bar{D} + (\bar{F} + \bar{G})\bar{E}$$

$$= ABC + \bar{D} + \bar{E}\bar{F} + \bar{E}\bar{G}$$

Exercise 2.28

Two possible options are shown below:

Y CD \ AB	AB			
	00	01	11	10
00	X	0	1	1
01	X	X	1	0
11	0	X	1	1
10	X	0	X	X

(a) $Y = A\bar{D} + AC + BD$

Y CD \ AB	AB			
	00	01	11	10
00	X	0	1	1
01	X	X	1	0
11	0	X	1	1
10	X	0	X	X

(b) $Y = A(B + C + \bar{D})$

Exercise 2.29

Two possible options are shown below:

Exercise 2.30

Option (a) could have a glitch when $A=1$, $B=1$, $C=0$, and D transitions from 1 to 0. The glitch could be removed by instead using the circuit in option (b).

Option (b) does not have a glitch. Only one path exists from any given input to the output.

Exercise 2.31

$$Y = \bar{A}D + A\bar{B}\bar{C}\bar{D} + BD + CD = A\bar{B}\bar{C}\bar{D} + D(\bar{A} + B + C)$$

Exercise 2.32

Exercise 2.33

The equation can be written directly from the description:

$$E = \bar{S}\bar{A} + AL + H$$

Exercise 2.34

(a)

(c)

Exercise 2.35

Decimal Value	A_3	A_2	A_1	A_0	D	P
0	0	0	0	0	0	0
1	0	0	0	1	0	0
2	0	0	1	0	0	1
3	0	0	1	1	1	1
4	0	1	0	0	0	0
5	0	1	0	1	0	1
6	0	1	1	0	1	0
7	0	1	1	1	0	1
8	1	0	0	0	0	0
9	1	0	0	1	1	0
10	1	0	1	0	0	0
11	1	0	1	1	0	1
12	1	1	0	0	1	0
13	1	1	0	1	0	1
14	1	1	1	0	0	0
15	1	1	1	1	1	0

P has two possible minimal solutions:

D $A_{1,0} \backslash A_{3,2}$	00	01	11	10
00	0	0	1	0
01	0	0	0	1
11	1	0	1	0
10	0	1	0	0

$$D = \overline{A}_3 \overline{A}_2 A_1 A_0 + \overline{A}_3 A_2 A_1 \overline{A}_0 + A_3 \overline{A}_2 \overline{A}_1 A_0 + A_3 A_2 \overline{A}_1 \overline{A}_0 + A_3 A_2 A_1 A_0$$

P $A_{1,0} \backslash A_{3,2}$	00	01	11	10
00	0	0	0	0
01	0	1	1	0
11	1	1	0	1
10	1	0	0	0

$$P = \overline{A}_3 \overline{A}_2 A_0 + \overline{A}_3 A_1 A_0 + \overline{A}_3 \overline{A}_2 A_1 + \overline{A}_2 A_1 A_0$$
$$P = \overline{A}_3 A_1 A_0 + \overline{A}_3 \overline{A}_2 A_1 + \overline{A}_2 A_1 A_0 + \overline{A}_2 \overline{A}_1 A_0$$

Hardware implementations are below (implementing the first minimal equation given for P).

Exercise 2.36

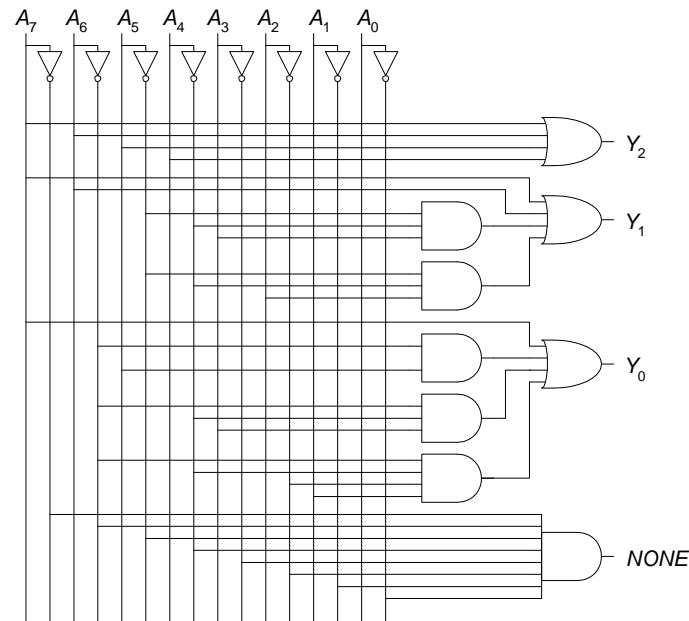

A_7	A_6	A_5	A_4	A_3	A_2	A_1	A_0	Y_2	Y_1	Y_0	NONE

1	1	X	X	X	X	X	X	1	1	0

$$Z_2 = A_4(A_5 + A_6 + A_7) + A_5(A_6 + A_7) + A_6A_7$$

$$Z_1 = A_2(A_3 + A_4 + A_5 + A_6 + A_7) + A_3(A_4 + A_5 + A_6 + A_7) + A_6A_7$$

$$Z_0 = A_1(A_2 + A_3 + A_4 + A_5 + A_6 + A_7) + A_3(A_4 + A_5 + A_6 + A_7) + A_5(A_6 + A_7)$$

Exercise 2.38

$$Y_6 = A_2A_1A_0$$

$$Y_5 = A_2A_1$$

$$Y_4 = A_2A_1 + A_2A_0$$

$$Y_3 = A_2$$

$$Y_2 = A_2 + A_1A_0$$

$$Y_1 = A_2 + A_1$$

$$Y_0 = A_2 + A_1 + A_0$$

Exercise 2.39

$$Y = A + \overline{C \oplus D} = A + CD + \overline{C}\overline{D}$$

Exercise 2.40

$$Y = \overline{\overline{C}\overline{D}}(A \oplus B) + \overline{\overline{A}\overline{B}} = \overline{\overline{A}\overline{C}\overline{D}} + \overline{\overline{B}\overline{C}\overline{D}} + \overline{\overline{A}\overline{B}}$$

Exercise 2.41

Exercise 2.42

Exercise 2.43

$$t_{pd} = 3t_{pd_NAND2} = \mathbf{60\ ps}$$

$$t_{cd} = t_{cd_NAND2} = \mathbf{15\ ps}$$

Exercise 2.44

$$\begin{aligned} t_{pd} &= t_{pd_AND2} + 2t_{pd_NOR2} + t_{pd_NAND2} \\ &= [30 + 2(30) + 20]\ ps \\ &= \mathbf{110\ ps} \end{aligned}$$

$$\begin{aligned} t_{cd} &= 2t_{cd_NAND2} + t_{cd_NOR2} \\ &= [2(15) + 25]\ ps \\ &= \mathbf{55\ ps} \end{aligned}$$

Exercise 2.45

$$\begin{aligned}t_{pd} &= t_{pd_NOT} + t_{pd_AND3} \\&= 15 \text{ ps} + 40 \text{ ps} \\&= \mathbf{55 \text{ ps}} \\t_{cd} &= t_{cd_AND3} \\&= \mathbf{30 \text{ ps}}\end{aligned}$$

Exercise 2.46

$$\begin{aligned} t_{pd} &= t_{pd_NOR2} + t_{pd_AND3} + t_{pd_NOR3} + t_{pd_NAND2} \\ &= [30 + 40 + 45 + 20] \text{ ps} \\ &= \mathbf{135 \text{ ps}} \end{aligned}$$

$$\begin{aligned} t_{cd} &= 2t_{cd_NAND2} + t_{cd_OR2} \\ &= [2 (15) + 30] \text{ ps} \\ &= \mathbf{60 \text{ ps}} \end{aligned}$$

Exercise 2.47

$$\begin{aligned}
 t_{pd} &= t_{pd_INV} + 3t_{pd_NAND2} + t_{pd_NAND3} \\
 &= [15 + 3(20) + 30] \text{ ps} \\
 &= \mathbf{105 \text{ ps}}
 \end{aligned}$$

$$\begin{aligned}
 t_{cd} &= t_{cd_NOT} + t_{cd_NAND2} \\
 &= [10 + 15] \text{ ps} \\
 &= \mathbf{25 \text{ ps}}
 \end{aligned}$$

Exercise 2.48

$$t_{pd_dy} = t_{pd_TRI_AY} \\ = \mathbf{50 \text{ ps}}$$

Note: the propagation delay from the control (select) input to the output is the circuit's critical path:

$$t_{pd_sy} = t_{pd_NOT} + t_{pd_AND3} + t_{pd_TRI_SY} \\ = [30 + 80 + 35] \text{ ps} \\ = \mathbf{145 \text{ ps}}$$

However, the problem specified to minimize the delay from data inputs to output, t_{pd_dy} .

Question 2.1

Question 2.2

    A0 --- XOR
    XOR --- Y
```

Question 2.3

A tristate buffer has two inputs and three possible outputs: 0, 1, and Z. One of the inputs is the data input and the other input is a control input, often called the *enable* input. When the enable input is 1, the tristate buffer transfers the data input to the output; otherwise, the output is high impedance, Z. Tristate buffers are used when multiple sources drive a single output at different times. One and only one tristate buffer is enabled at any given time.

Question 2.4

(a) An AND gate is not universal, because it cannot perform inversion (NOT).

(b) The set {OR, NOT} is universal. It can construct any Boolean function. For example, an OR gate with NOT gates on all of its inputs and output performs the AND operation. Thus, the set {OR, NOT} is equivalent to the set {AND, OR, NOT} and is universal.

(c) The NAND gate by itself is universal. A NAND gate with its inputs tied together performs the NOT operation. A NAND gate with a NOT gate on its output performs AND. And a NAND gate with NOT gates on its inputs performs OR. Thus, a NAND gate is equivalent to the set {AND, OR, NOT} and is universal.

Question 2.5

A circuit's contamination delay might be less than its propagation delay because the circuit may operate over a range of temperatures and supply voltages, for example, 3-3.6 V for LVCMOS (low voltage CMOS) chips. As temperature increases and voltage decreases, circuit delay increases. Also, the circuit may have different paths (critical and short paths) from the input to the output. A gate itself may have varying delays between different inputs and the output, affecting the gate's critical and short paths. For example, for a two-input NAND gate, a HIGH to LOW transition requires two nMOS transistor delays, whereas a LOW to HIGH transition requires a single pMOS transistor delay.

CHAPTER 3

Exercise 3.1

Exercise 3.2

Exercise 3.3

Exercise 3.4

Exercise 3.5

Exercise 3.6

Exercise 3.7

The circuit is sequential because it involves feedback and the output depends on previous values of the inputs. This is a SR latch. When $\bar{S} = 0$ and $\bar{R} = 1$, the circuit sets Q to 1. When $\bar{S} = 1$ and $\bar{R} = 0$, the circuit resets Q to 0. When both \bar{S} and \bar{R} are 1, the circuit remembers the old value. And when both \bar{S} and \bar{R} are 0, the circuit drives both outputs to 1.

Exercise 3.8

Sequential logic. This is a D flip-flop with active low asynchronous set and reset inputs. If \bar{S} and \bar{R} are both 1, the circuit behaves as an ordinary D flip-flop. If $\bar{S} = 0$, Q is immediately set to 0. If $\bar{R} = 0$, Q is immediately reset to 1. (This circuit is used in the commercial 7474 flip-flop.)

Exercise 3.9

Exercise 3.10

Exercise 3.11

If A and B have the same value, C takes on that value. Otherwise, C retains its old value.

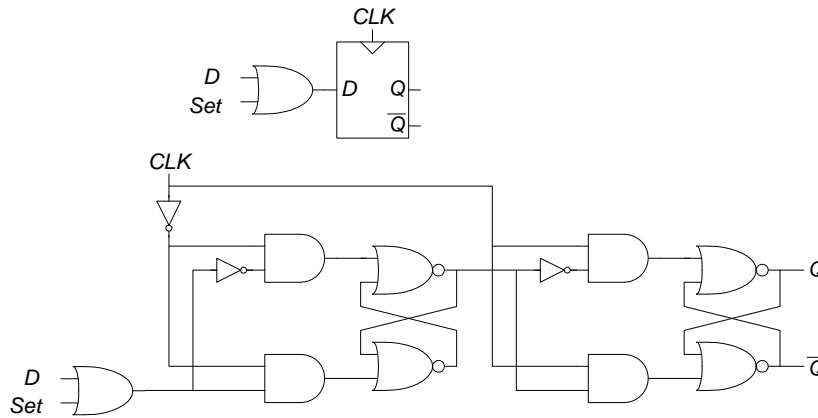

Exercise 3.12

Exercise 3.13

Exercise 3.14

Exercise 3.15

Exercise 3.16

From $\frac{1}{2Nt_{pd}}$ to $\frac{1}{2Nt_{cd}}$.

Exercise 3.17

If N is even, the circuit is stable and will not oscillate.

Exercise 3.18

(a) No: no register. (b) No: feedback without passing through a register. (c) Yes. Satisfies the definition. (d) Yes. Satisfies the definition.

Exercise 3.19

The system has at least five bits of state to represent the 24 floors that the elevator might be on.

Exercise 3.20

The FSM has $5^4 = 625$ states. This requires at least 10 bits to represent all the states.

Exercise 3.21

The FSM could be factored into four independent state machines, one for each student. Each of these machines has five states and requires 3 bits, so at least 12 bits of state are required for the factored design.

Exercise 3.22

This finite state machine asserts the output Q for one clock cycle if A is TRUE followed by B being TRUE.

$$Z = BA + S_0(A + B)$$

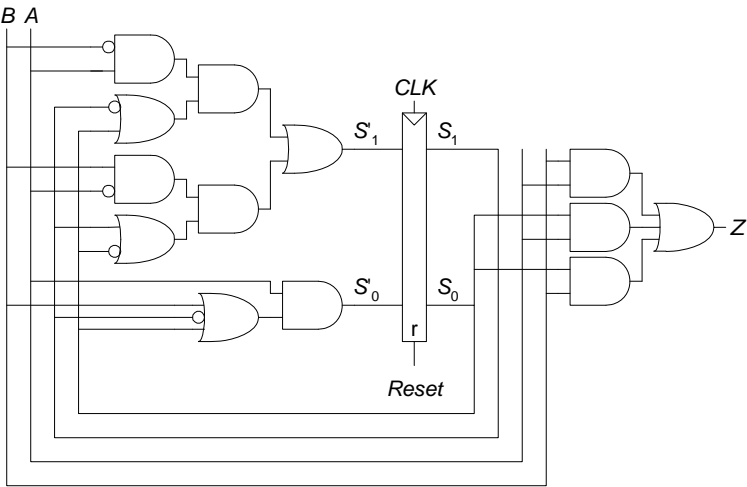

FIGURE 3.10 Hardware for FSM of Exercise 3.26

Note: One could also build this functionality by registering input A, producing both the logical AND and OR of input A and its previous (registered)

value, and then muxing the two operations using B . The output of the mux is Z :
 $Z = A\overline{A}_{\text{prev}}$ (if $B = 0$); $Z = A + A_{\text{prev}}$ (if $B = 1$).

TABLE 3.20 State transition table with binary encodings for Exercise 3.32

FIGURE 3.13 State transition diagram for Exercise 3.32

Q asserts whenever A is HIGH for two or more consecutive cycles.

Exercise 3.33

(a) First, we calculate the propagation delay through the combinational logic:

$$\begin{aligned}
 t_{pd} &= 3t_{pd_XOR} \\
 &= 3 \times 100 \text{ ps} \\
 &= \mathbf{300 \text{ ps}}
 \end{aligned}$$

Next, we calculate the cycle time:

$$\begin{aligned}
 T_c &\geq t_{pcq} + t_{pd} + t_{\text{setup}} \\
 &\geq [70 + 300 + 60] \text{ ps} \\
 &= 430 \text{ ps}
 \end{aligned}$$

$$f = 1 / 430 \text{ ps} = \mathbf{2.33 \text{ GHz}}$$

(b)

$$T_c \geq t_{pcq} + t_{pd} + t_{\text{setup}} + t_{\text{skew}}$$

Thus,

$$\begin{aligned}
 t_{\text{skew}} &\leq T_c - (t_{pcq} + t_{pd} + t_{\text{setup}}), \text{ where } T_c = 1 / 2 \text{ GHz} = 500 \text{ ps} \\
 &\leq [500 - 430] \text{ ps} = \mathbf{70 \text{ ps}}
 \end{aligned}$$

(c)

$$\begin{aligned} t_{cd} &= t_{cd_XOR} \\ &= 55 \text{ ps} \end{aligned}$$

Thus,

$$\begin{aligned} t_{\text{skew}} &< (t_{ccq} + t_{cd}) - t_{\text{hold}} \\ &< (50 + 55) - 20 \\ &< \mathbf{85 \text{ ps}} \end{aligned}$$

(d)

FIGURE 3.14 Alyssa's improved circuit for Exercise 3.33

$$\begin{aligned} t_{pd} &= 2t_{pd_XOR} \\ &= 2 \times 100 \text{ ps} \\ &= \mathbf{200 \text{ ps}} \end{aligned}$$

$$\begin{aligned} t_{cd} &= 2t_{cd_XOR} \\ &= 2 \times 55 \text{ ps} \\ &= \mathbf{110 \text{ ps}} \end{aligned}$$

$$\begin{aligned} T_c &\geq t_{pcq} + t_{pd} + t_{\text{setup}} \\ &\geq [70 + 200 + 60] \text{ ps} \\ &= 330 \text{ ps} \end{aligned}$$

$$f = 1 / 330 \text{ ps} = \mathbf{3.03 \text{ GHz}}$$

$$\begin{aligned} t_{\text{skew}} &< (t_{ccq} + t_{cd}) - t_{\text{hold}} \\ &< (50 + 110) - 20 \\ &< \mathbf{140 \text{ ps}} \end{aligned}$$

Exercise 3.34

- (a) 9.09 GHz
- (b) 15 ps
- (c) 26 ps

Exercise 3.35

- (a) $T_c = 1 / 40 \text{ MHz} = 25 \text{ ns}$
 $T_c \geq t_{pcq} + Nt_{CLB} + t_{setup}$
 $25 \text{ ns} \geq [0.72 + N(0.61) + 0.53] \text{ ps}$
 Thus, $N < 38.9$
 $N = 38$

- (b)
 $t_{skew} < (t_{ccq} + t_{cd_CLB}) - t_{hold}$
 $< [(0.5 + 0.3) - 0] \text{ ns}$
 $< 0.8 \text{ ns} = 800 \text{ ps}$

Exercise 3.36

1.138 ns

Exercise 3.37

$P(\text{failure})/\text{sec} = 1/\text{MTBF} = 1/(50 \text{ years} * 3.15 \times 10^7 \text{ sec/year}) = \mathbf{6.34 \times 10^{-10}}$ (EQ 3.26)

$P(\text{failure})/\text{sec}$ waiting for one clock cycle: $N*(T_0/T_c)*e^{-(T_c-t_{setup})/\tau}$

$$= 0.5 * (110/1000) * e^{-(1000-70)/100} = 5.0 \times 10^{-6}$$

$P(\text{failure})/\text{sec}$ waiting for two clock cycles: $N*(T_0/T_c)*[e^{-(T_c-t_{setup})/\tau}]^2$

$$= 0.5 * (110/1000) * [e^{-(1000-70)/100}]^2 = 4.6 \times 10^{-10}$$

This is just less than the required probability of failure (6.34×10^{-10}). Thus, **2 cycles** of waiting is just adequate to meet the MTBF.

Exercise 3.38

(a) You know you've already entered metastability, so the probability that the sampled signal is metastable is 1. Thus,

$$P(\text{failure}) = 1 \times e^{-\frac{t}{\tau}}$$

Solving for the probability of still being metastable (failing) to be 0.01:

$$P(\text{failure}) = e^{-\frac{t}{\tau}} = 0.01$$

Thus,

$$t = -\tau \times \ln(P(\text{failure})) = -20 \times \ln((0.01)) = \mathbf{92 \text{ seconds}}$$

(b) The probability of death is the chance of still being metastable after 3 minutes

$$P(\text{failure}) = 1 \times e^{-(3 \text{ min} \times 60 \text{ sec}) / 20 \text{ sec}} = \mathbf{0.000123}$$

Exercise 3.39

We assume a two flip-flop synchronizer. The most significant impact on the probability of failure comes from the exponential component. If we ignore the T_0/T_c term in the probability of failure equation, assuming it changes little with increases in cycle time, we get:

$$P(\text{failure}) = e^{-\frac{t}{\tau}}$$

$$MTBF = \frac{1}{P(\text{failure})} = e^{\frac{T_c - t_{\text{setup}}}{\tau}}$$

$$\frac{MTBF_2}{MTBF_1} = 10 = e^{\frac{T_{c2} - T_{c1}}{30ps}}$$

Solving for $T_{c2} - T_{c1}$, we get:

$$T_{c2} - T_{c1} = 69ps$$

Thus, the clock cycle time must increase by **69 ps**. This holds true for cycle times much larger than T_0 (20 ps) and the increased time (69 ps).

Exercise 3.40

Alyssa is correct. Ben's circuit does not eliminate metastability. After the first transition on D, D2 is always 0 because as D2 transitions from 0 to 1 or 1 to 0, it enters the forbidden region and Ben's "metastability detector" resets the first flip-flop to 0. Even if Ben's circuit could correctly detect a metastable output, it would asynchronously reset the flip-flop which, if the reset occurred around the clock edge, this could cause the second flip-flop to sample a transitioning signal and become metastable.

Question 3.1

 $S'_1 = A(S_1 + S_3 + S_5)$
 $S'_0 = A(S_0 + S_2 + S_4 + S_5)$
 $Q = S_5$

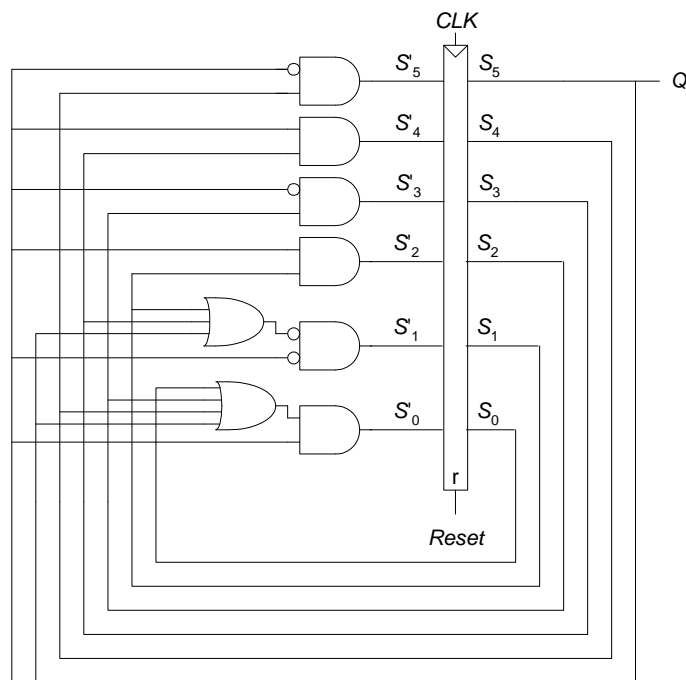

FIGURE 3.16 Finite state machine hardware for Question 3.1

Question 3.2

The FSM should output the value of A until after the first 1 is received. It then should output the inverse of A . For example, the 8-bit two's complement of the number 6 (00000110) is (11111010). Starting from the least significant bit on the far right, the two's complement is created by outputting the same value of the input until the first 1 is reached. Thus, the two least significant bits of the two's complement number are "10". Then the remaining bits are inverted, making the complete number 11111010.

$$S'_0 = A \oplus (S_1 + S_0)$$

$$Q = S_0$$

FIGURE 3.18 Finite state machine hardware for Question 3.2

Question 3.3

A latch allows input D to flow through to the output Q when the clock is HIGH. A flip-flop allows input D to flow through to the output Q at the clock edge. A flip-flop is preferable in systems with a single clock. Latches are preferable in *two-phase clocking* systems, with two clocks. The two clocks are used to eliminate system failure due to hold time violations. Both the phase and frequency of each clock can be modified independently.

FIGURE 3.22 Finite state machine hardware for Question 3.5

Question 3.6

Pipelining divides a block of combinational logic into N stages, with a register between each stage. Pipelining increases throughput, the number of tasks that can be completed in a given amount of time. Ideally, pipelining increases throughput by a factor of N . But because of the following three reasons, the

speedup is usually less than N : (1) The combinational logic usually cannot be divided into N equal stages. (2) Adding registers between stages adds delay called the *sequencing overhead*, the time it takes to get the signal into and out of the register, $t_{\text{setup}} + t_{\text{pcq}}$. (3) The pipeline is not always operating at full capacity: at the beginning of execution, it takes time to fill up the pipeline, and at the end it takes time to drain the pipeline. However, pipelining offers significant speedup at the cost of little extra hardware.

Question 3.7

A flip-flop with a negative hold time allows D to start changing *before* the clock edge arrives.

Question 3.8

We use a divide-by-three counter (see Example 3.6 on page 155 of the text-book) with A as the clock input followed by a *negative edge-triggered* flip-flop, which samples the input, D , on the negative or falling edge of the clock, or in this case, A . The output is the output of the divide-by-three counter, S_0 , OR the output of the negative edge-triggered flip-flop, $N1$. Figure 3.24 shows the waveforms of the internal signals, S_0 and $N1$.

FIGURE 3.23 Hardware for Question 3.8

FIGURE 3.24 Waveforms for Question 3.8

Question 3.9

Without the added buffer, the propagation delay through the logic, t_{pd} , must be less than or equal to $T_c - (t_{pcq} + t_{setup})$. However, if you add a buffer to the clock input of the receiver, the clock arrives at the receiver later. The earliest that the clock edge arrives at the receiver is t_{cd_BUF} after the actual clock edge. Thus, the propagation delay through the logic is now given an extra t_{cd_BUF} . So, t_{pd} now must be less than $T_c + t_{cd_BUF} - (t_{pcq} + t_{setup})$.

            when S00 => if x then
                            nextstate <= S11;
                        else nextstate <= S01;
                        end if;
            when S01 => if x then
                            nextstate <= S10;
                        else nextstate <= S00;
                        end if;
            when S10 =>      nextstate <= S01;
            when S11 =>      nextstate <= S01;
            when others =>   nextstate <= S00;
        end case;
    end process;

    -- output logic
    q <= '0' when (state = S00) else '1';
end;
```

Exercise 4.43

SystemVerilog

```
module ex4_43(input  clk, reset, a,
              output q);
    typedef enum logic [1:0] {S0, S1, S2} statetype;
    statetype [1:0] state, nextstate;

    // State Register
    always_ff @(posedge clk, posedge reset)
        if (reset) state <= S0;
        else      state <= nextstate;

    // Next State Logic
    always_comb
        case (state)
            S0: if (a) nextstate = S1;
                else nextstate = S0;
            S1: if (a) nextstate = S2;
                else nextstate = S0;
            S2: if (a) nextstate = S2;
                else nextstate = S0;
            default: nextstate = S0;
        endcase

    // Output Logic
    assign q = state[1];
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity ex4_43 is
    port(clk, reset, a: in  STD_LOGIC;
         q: out STD_LOGIC);
end;

architecture synth of ex4_43 is
    type statetype is (S0, S1, S2);
    signal state, nextstate: statetype;
begin
    -- state register
    process(clk, reset) begin
        if reset then state <= S0;
        elsif rising_edge(clk) then
            state <= nextstate;
        end if;
    end process;

    -- next state logic
    process(all) begin
        case state is
            when S0 => if a then
                            nextstate <= S1;
                        else nextstate <= S0;
                        end if;
            when S1 => if a then
                            nextstate <= S2;
                        else nextstate <= S0;
                        end if;
            when S2 => if a then
                            nextstate <= S2;
                        else nextstate <= S0;
                        end if;
            when others => nextstate <= S0;
        end case;
    end process;

    -- output logic
    q <= '1' when (state = S2) else '0';
end;
```

Exercise 4.44

(a)

SystemVerilog

```
module ex4_44a(input logic clk, a, b, c, d,
              output logic q);

    logic areg, breg, creg, dreg;

    always_ff @(posedge clk)
    begin
        areg <= a;
        breg <= b;
        creg <= c;
        dreg <= d;
        q    <= ((areg ^ breg) ^ creg) ^ dreg;
    end
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity ex4_44a is
    port(clk, a, b, c, d: in  STD_LOGIC;
          q:                  out STD_LOGIC);
end;

architecture synth of ex4_44a is
    signal areg, breg, creg, dreg: STD_LOGIC;
begin
    process(clk) begin
        if rising_edge(clk) then
            areg <= a;
            breg <= b;
            creg <= c;
            dreg <= d;
            q <= ((areg xor breg) xor creg) xor dreg;
        end if;
    end process;
end;
```

(d)

SystemVerilog

```
module ex4_44d(input logic clk, a, b, c, d,
              output logic q);

    logic areg, breg, creg, dreg;

    always_ff @(posedge clk)
    begin
        areg <= a;
        breg <= b;
        creg <= c;
        dreg <= d;
        q    <= (areg ^ breg) ^ (creg ^ dreg);
    end
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity ex4_44d is
    port(clk, a, b, c, d: in  STD_LOGIC;
          q:                  out STD_LOGIC);
end;

architecture synth of ex4_44d is
    signal areg, breg, creg, dreg: STD_LOGIC;
begin
    process(clk) begin
        if rising_edge(clk) then
            areg <= a;
            breg <= b;
            creg <= c;
            dreg <= d;
            q <= (areg xor breg) xor (creg xor dreg);
        end if;
    end process;
end;
```

SystemVerilog

```
module ex4_45(input logic clk, c,
             input logic [1:0] a, b,
             output logic [1:0] s);

    logic [1:0] areg, breg;
    logic creg;
    logic [1:0] sum;
    logic cout;

    always_ff @(posedge clk)
        {areg, breg, creg, s} <= {a, b, c, sum};

    fulladder fulladd1(areg[0], breg[0], creg,
                     sum[0], cout);
    fulladder fulladd2(areg[1], breg[1], cout,
                     sum[1], );
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity ex4_45 is
    port(clk, c: in STD_LOGIC;
         a, b: in STD_LOGIC_VECTOR(1 downto 0);
         s: out STD_LOGIC_VECTOR(1 downto 0));
end;

architecture synth of ex4_45 is
    component fulladder is
        port(a, b, cin: in STD_LOGIC;
             s, cout: out STD_LOGIC);
    end component;
    signal creg: STD_LOGIC;
    signal areg, breg, cout: STD_LOGIC_VECTOR(1 downto 0);
    signal sum: STD_LOGIC_VECTOR(1 downto 0);
begin
    process(clk) begin
        if rising_edge(clk) then
            areg <= a;
            breg <= b;
            creg <= c;
            s <= sum;
        end if;
    end process;

    fulladd1: fulladder
        port map(areg(0), breg(0), creg, sum(0), cout(0));
    fulladd2: fulladder
        port map(areg(1), breg(1), cout(0), sum(1),
        cout(1));
end;
```

Exercise 4.46

A signal declared as `tri` can have multiple drivers.

Exercise 4.47

SystemVerilog

```
module syncbad(input  logic clk,
               input  logic d,
               output logic q);

    logic n1;

    always_ff @(posedge clk)
        begin
            q  <= n1; // nonblocking
            n1 <= d;  // nonblocking
        end
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity syncbad is
    port(clk: in  STD_LOGIC;
          d:  in  STD_LOGIC;
          q:  out STD_LOGIC);
end;

architecture bad of syncbad is
begin
    process(clk)
        variable n1: STD_LOGIC;
    begin
        if rising_edge(clk) then
            q  <= n1; -- nonblocking
            n1 <= d;  -- nonblocking
        end if;
    end process;
end;
```

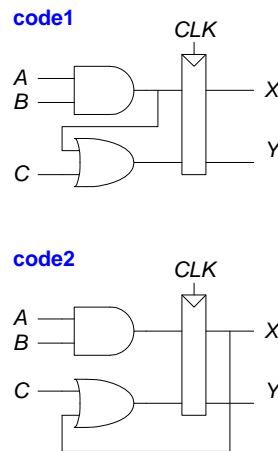

Exercise 4.48

They have the same function.

Exercise 4.49

They do not have the same function.

Exercise 4.50

(a) Problem: Signal `d` is not included in the sensitivity list of the `always` statement. Correction shown below (changes are in bold).

```
module latch(input  logic    clk,
             input  logic [3:0] d,
             output logic [3:0] q);

    always_latch
        if (clk) q <= d;
endmodule
```

(b) Problem: Signal `b` is not included in the sensitivity list of the `always` statement. Correction shown below (changes are in bold).

```
module gates(input  logic [3:0] a, b,
             output logic [3:0] y1, y2, y3, y4, y5);

    always_comb
    begin
        y1 = a & b;
        y2 = a | b;
        y3 = a ^ b;
        y4 = ~(a & b);
        y5 = ~(a | b);
    end
endmodule
```

(c) Problem: The sensitivity list should not include the word “posedge”. The `always` statement needs to respond to any changes in `s`, not just the positive edge. Signals `d0` and `d1` need to be added to the sensitivity list. Also, the `always` statement implies combinational logic, so blocking assignments should be used.

```
module mux2(input logic [3:0] d0, d1,
            input logic s,
            output logic [3:0] y);

    always_comb
        if (s) y = d1;
        else y = d0;
endmodule
```

(d) Problem: This module will actually work in this case, but it's good practice to use nonblocking assignments in `always` statements that describe sequential logic. Because the `always` block has more than one statement in it, it requires a `begin` and `end`.

```
module twoflops(input logic clk,
                input logic d0, d1,
                output logic q0, q1);

    always_ff @(posedge clk)
    begin
        q1 <= d1;           // nonblocking assignment
        q0 <= d0;           // nonblocking assignment
    end
endmodule
```

(e) Problem: `out1` and `out2` are not assigned for all cases. Also, it would be best to separate the next state logic from the state register. `reset` is also missing in the input declaration.

```
module FSM(input logic clk,
            input logic reset,
            input logic a,
            output logic out1, out2);

    logic state, nextstate;

    // state register
    always_ff @(posedge clk, posedge reset)
    if (reset)
        state <= 1'b0;
    else
        state <= nextstate;

    // next state logic
    always_comb
    case (state)
        1'b0: if (a) nextstate = 1'b1;
              else nextstate = 1'b0;
        1'b1: if (~a) nextstate = 1'b0;
              else nextstate = 1'b1;
    endcase

    // output logic (combinational)
    always_comb
    if (state == 0) {out1, out2} = {1'b1, 1'b0};
    else
        {out1, out2} = {1'b0, 1'b1};
endmodule
```

(f) Problem: A priority encoder is made from combinational logic, so the HDL must completely define what the outputs are for all possible input combinations. So, we must add an `else` statement at the end of the `always` block.

```
module priority(input logic [3:0] a,
```

```

        output logic [3:0] y);

    always_comb
    if      (a[3]) y = 4'b1000;
    else if (a[2]) y = 4'b0100;
    else if (a[1]) y = 4'b0010;
    else if (a[0]) y = 4'b0001;
    else      y = 4'b0000;
endmodule

```

(g) Problem: the next state logic block has no default statement. Also, state S2 is missing the S.

```

module divideby3FSM(input  logic clk,
                   input  logic reset,
                   output logic out);

    logic [1:0] state, nextstate;

    parameter S0 = 2'b00;
    parameter S1 = 2'b01;
    parameter S2 = 2'b10;

    // State Register
    always_ff @(posedge clk, posedge reset)
    if (reset) state <= S0;
    else      state <= nextstate;

    // Next State Logic
    always_comb
    case (state)
        S0:      nextstate = S1;
        S1:      nextstate = S2;
        S2:      nextstate = S0;
        default: nextstate = S0;
    endcase

    // Output Logic
    assign out = (state == S2);
endmodule

```

(h) Problem: the ~ is missing on the first tristate.

```

module mux2tri(input  logic [3:0] d0, d1,
              input  logic s,
              output logic [3:0] y);

    tristate t0(d0, ~s, y);
    tristate t1(d1, s, y);

endmodule

```

(i) Problem: an output, in this case, q, cannot be assigned in multiple always or assignment statements. Also, the flip-flop does not include an enable, so it should not be named floprsen.

```

module floprs(input  logic clk,
             input  logic reset,
             input  logic set,
             input  logic [3:0] d,
             output logic [3:0] q);

    always_ff @(posedge clk, posedge reset, posedge set)

```

```
        if (reset)    q <= 0;
        else if (set) q <= 1;
        else          q <= d;
    endmodule
```

(j) **Problem:** this is a combinational module, so nonconcurrent (blocking) assignment statements (=) should be used in the always statement, not concurrent assignment statements (<=). Also, it's safer to use always @(*) for combinational logic to make sure all the inputs are covered.

```
module and3(input  logic a, b, c,
            output logic y);

    logic tmp;

    always_comb
    begin
        tmp = a & b;
        y   = tmp & c;
    end
endmodule
```

Exercise 4.51

It is necessary to write

```
q <= '1' when state = S0 else '0';
```

rather than simply

```
q <= (state = S0);
```

because the result of the comparison (state = S0) is of type Boolean (true and false) and q must be assigned a value of type STD_LOGIC ('1' and '0').

Exercise 4.52

(a) **Problem:** both clk and d must be in the process statement.

```
architecture synth of latch is
begin
    process(clk, d) begin
        if clk = '1' then q <= d;
        end if;
    end process;
end;
```

(b) **Problem:** both a and b must be in the process statement.

```
architecture proc of gates is
begin
    process(all) begin
        y1 <= a and b;
        y2 <= a or b;
        y3 <= a xor b;
    end process;
end;
```

```

    y4 <= a nand b;
    y5 <= a nor b;
end process;
end;
```

(c) **Problem:** The end if and end process statements are missing.

```

architecture synth of flop is
begin
    process(clk)
        if clk'event and clk = '1' then
            q <= d;
        end if;
    end process;
end;
```

(d) **Problem:** The final else statement is missing. Also, it's better to use "process(all)" instead of "process(a)"

```

architecture synth of priority is
begin
    process(all) begin
        if a(3) = '1' then y <= "1000";
        elsif a(2) = '1' then y <= "0100";
        elsif a(1) = '1' then y <= "0010";
        elsif a(0) = '1' then y <= "0001";
        else y <= "0000";
        end if;
    end process;
end;
```

(e) **Problem:** The default statement is missing in the nextstate case statement. Also, it's better to use the updated statements: "if reset", "rising_edge(clk)", and "process(all)".

```

architecture synth of divideby3FSM is
    type statetype is (S0, S1, S2);
    signal state, nextstate: statetype;
begin
    process(clk, reset) begin
        if reset then state <= S0;
        elsif rising_edge(clk) then
            state <= nextstate;
        end if;
    end process;

    process(all) begin
        case state is
            when S0 => nextstate <= S1;
            when S1 => nextstate <= S2;
            when S2 => nextstate <= S0;
            when others => nextstate <= S0;
        end case;
    end process;

    q <= '1' when state = S0 else '0';
end;
```

(f) **Problem:** The select signal on tristate instance t0 must be inverted. However, VHDL does not allow logic to be performed within an instance declaration. Thus, an internal signal, sbar, must be declared.

```

architecture struct of mux2 is
    component tristate
```

```
        port(a: in  STD_LOGIC_VECTOR(3 downto 0);
              en: in  STD_LOGIC;
              y: out STD_LOGIC_VECTOR(3 downto 0));
    end component;
    signal sbar: STD_LOGIC;
begin
    sbar <= not s;
    t0: tristate port map(d0, sbar, y);
    t1: tristate port map(d1, s, y);
end;
```

(g) **Problem:** The q output cannot be assigned in two process or assignment statements. Also, it's better to use the updated statements: “if reset”, and “rising_edge(clk)”.

```
architecture asynchronous of flopr is
begin
    process(clk, reset, set) begin
        if reset then
            q <= '0';
        elsif set then
            q <= '1';
        elsif rising_edge(clk) then
            q <= d;
        end if;
    end process;
end;
```

Question 4.1

SystemVerilog

```
assign result = sel ? data : 32'b0;
```

VHDL

```
result <= data when sel = '1' else X"00000000";
```

Question 4.2

HDLs support *blocking* and *nonblocking assignments* in an always / process statement. A group of blocking assignments are evaluated in the order they appear in the code, just as one would expect in a standard programming

language. A group of nonblocking assignments are evaluated concurrently; all of the statements are evaluated before any of the left hand sides are updated.

SystemVerilog

In a SystemVerilog `always` statement, `=` indicates a blocking assignment and `<=` indicates a nonblocking assignment.

Do not confuse either type with continuous assignment using the `assign` statement. `assign` statements are normally used outside `always` statements and are also evaluated concurrently.

VHDL

In a VHDL `process` statement, `:=` indicates a blocking assignment and `<=` indicates a nonblocking assignment (also called a concurrent assignment). This is the first section where `:=` is introduced.

Nonblocking assignments are made to outputs and to signals. Blocking assignments are made to variables, which are declared in `process` statements (see the next example).

`<=` can also appear outside `process` statements, where it is also evaluated concurrently.

See HDL Examples 4.24 and 4.29 for comparisons of blocking and nonblocking assignments. Blocking and nonblocking assignment guidelines are given on page 206.

Question 4.3

The SystemVerilog statement performs the bit-wise AND of the 16 least significant bits of data with 0xC820. It then ORs these 16 bits to produce the 1-bit result.

CHAPTER 5

Note: the HDL files given in the following solutions are available on the textbook's companion website at:

<http://textbooks.elsevier.com/9780123704979> .

Exercise 5.1

(a) From Equation 5.1, we find the 64-bit ripple-carry adder delay to be:

$$t_{\text{ripple}} = Nt_{\text{FA}} = 64(450 \text{ ps}) = 28.8 \text{ ns}$$

(b) From Equation 5.6, we find the 64-bit carry-lookahead adder delay to be:

$$t_{\text{CLA}} = t_{\text{pg}} + t_{\text{pg_block}} + \left(\frac{N}{k} - 1\right)t_{\text{AND_OR}} + kt_{\text{FA}}$$

$$t_{\text{CLA}} = \left[150 + (6 \times 150) + \left(\frac{64}{4} - 1\right)300 + (4 \times 450)\right] = 7.35 \text{ ns}$$

(Note: the actual delay is only 7.2 ns because the first AND_OR gate only has a 150 ps delay.)

(c) From Equation 5.11, we find the 64-bit prefix adder delay to be:

$$t_{\text{PA}} = t_{\text{pg}} + \log_2 N(t_{\text{pg_prefix}}) + t_{\text{XOR}}$$

$$t_{\text{PA}} = [150 + 6(300) + 150] = 2.1 \text{ ns}$$

Exercise 5.2

(a) The fundamental building block of both the ripple-carry and carry-lookahead adders is the full adder. We use the full adder from Figure 4.8, shown again here for convenience:

FIGURE 5.1 Full adder implementation

The full adder delay is three two-input gates.

$$t_{FA} = 3(50) \text{ ps} = 150 \text{ ps}$$

The full adder area is five two-input gates.

$$A_{FA} = 5(15 \mu m^2) = 75 \mu m^2$$

The full adder capacitance is five two-input gates.

$$C_{FA} = 5(20 \text{ fF}) = 100 \text{ fF}$$

Thus, the ripple-carry adder delay, area, and capacitance are:

$$t_{\text{ripple}} = N t_{FA} = 64(150 \text{ ps}) = 9.6 \text{ ns}$$

$$A_{\text{ripple}} = N A_{FA} = 64(75 \mu m^2) = 4800 \mu m^2$$

$$C_{\text{ripple}} = N C_{FA} = 64(100 \text{ fF}) = 6.4 \text{ pF}$$

Using the carry-lookahead adder from Figure 5.6, we can calculate delay, area, and capacitance. Using Equation 5.6:

$$t_{CLA} = [50 + 6(50) + 15(100) + 4(150)] \text{ ps} = 2.45 \text{ ns}$$

(The actual delay is only 2.4 ns because the first AND_OR gate only contributes one gate delay.)

For each 4-bit block of the 64-bit carry-lookahead adder, there are 4 full adders, 8 two-input gates to generate P_i and G_i , and 11 two-input gates to generate $P_{i:j}$ and $G_{i:j}$. Thus, the area and capacitance are:

$$A_{CLAblock} = [4(75) + 19(15)] \mu m^2 = 585 \mu m^2$$

$$A_{CLA} = 16(585) \mu m^2 = 9360 \mu m^2$$

$$C_{CLAblock} = [4(100) + 19(20)] \text{ fF} = 780 \text{ fF}$$

$$C_{CLA} = 16(780) \text{ fF} = 12.48 \text{ pF}$$

Now solving for power using Equation 1.4,

$$P_{\text{dynamic_ripple}} = \frac{1}{2} CV_{DD}^2 f = \frac{1}{2} (6.4 \text{ pF}) (1.2 \text{ V})^2 (100 \text{ MHz}) = 0.461 \text{ mW}$$

$$P_{\text{dynamic_CLA}} = \frac{1}{2} CV_{DD}^2 f = \frac{1}{2} (12.48 \text{ pF}) (1.2 \text{ V})^2 (100 \text{ MHz}) = 0.899 \text{ mW}$$

	ripple- carry	carry-lookahead	cla/ripple
Area (μm^2)	4800	9360	1.95
Delay (ns)	9.6	2.45	0.26
Power (mW)	0.461	0.899	1.95

TABLE 5.1 CLA and ripple-carry adder comparison

(b) Compared to the ripple-carry adder, the carry-lookahead adder is almost twice as large and uses almost twice the power, but is almost four times as fast. Thus for performance-limited designs where area and power are not constraints, the carry-lookahead adder is the clear choice. On the other hand, if either area or power are the limiting constraints, one would choose a ripple-carry adder if performance were not a constraint.

Exercise 5.3

A designer might choose to use a ripple-carry adder instead of a carry-lookahead adder if chip area is the critical resource and delay is not the critical constraint.

Exercise 5.4

SystemVerilog

```

Exercise 5.5

FIGURE 5.2 16-bit prefix adder with “gray cells”

Exercise 5.6

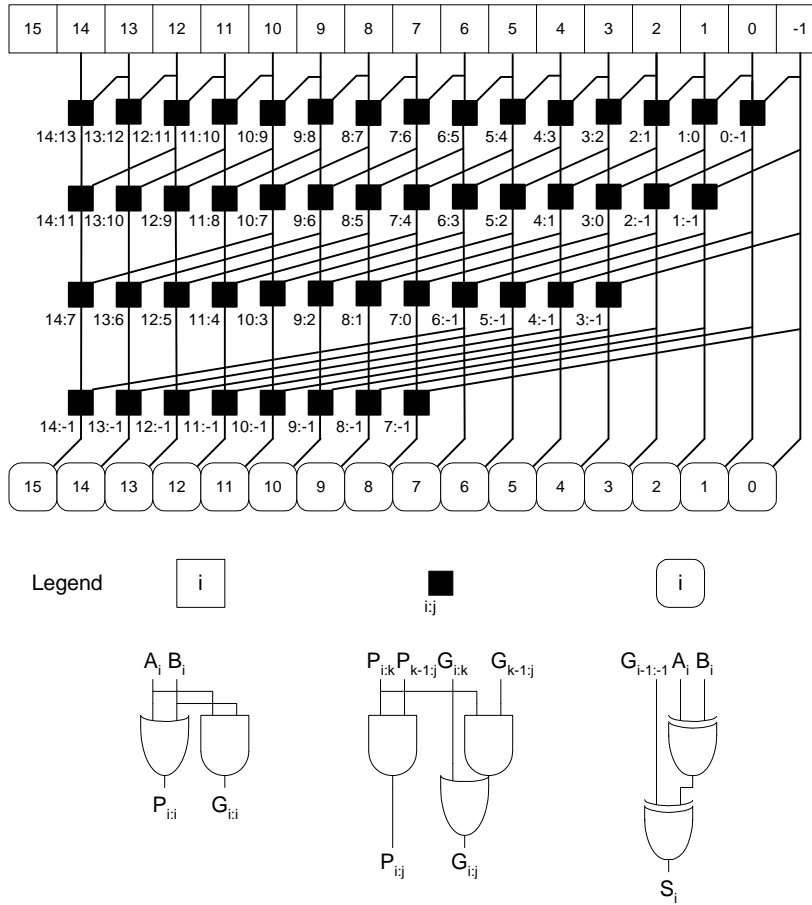

FIGURE 5.3 Schematic of a 16-bit Kogge-Stone adder

Exercise 5.7

(a) We show an 8-bit priority circuit in Figure 5.4. In the figure $X_7 = \bar{A}_7$, $X_{7:6} = \bar{A}_7\bar{A}_6$, $X_{7:5} = \bar{A}_7\bar{A}_6\bar{A}_5$, and so on. The priority encoder's delay is $\log_2 N$ 2-input AND gates followed by a final row of 2-input AND gates. The final stage is an $(N/2)$ -input OR gate. Thus, in general, the delay of an N -input priority encoder is:

$$t_{pd_priority} = (\log_2 N + 1)t_{pd_AND2} + t_{pd_ORN/2}$$

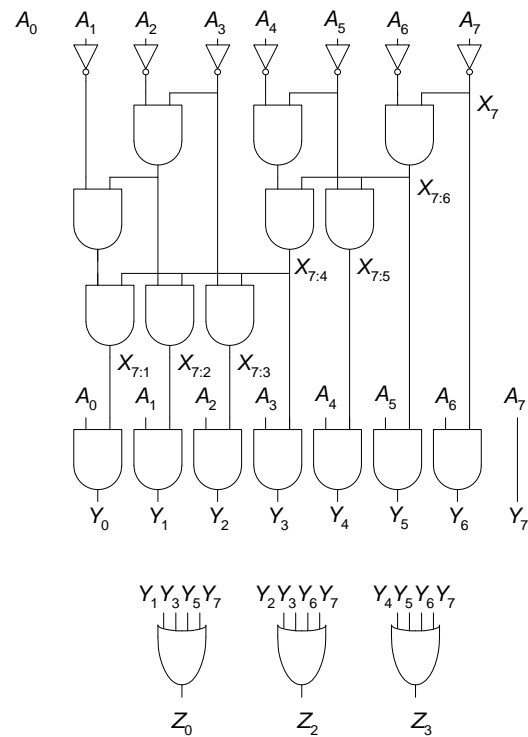

FIGURE 5.4 8-input priority encoder

            when others => Y <= X"000000000";
        end case;
    end process;
end;
```

Exercise 5.10

(a)

When adding:

- If both operands are positive and output is negative, overflow occurred.
- If both operands are negative and the output is positive, overflow occurred.

When subtracting:

- If the first operand is positive and the second is negative, if the output of the adder unit is negative, overflow occurred.
- If first operand is negative and second operand is positive, if the output of the adder unit is positive, overflow occurred.

In equation form:

Overflow = ADD & (A & B & ~S[31] | ~A & ~B & S[31]) |

$\text{SUB } \& (A \& \sim B \& \sim S[31] \mid \sim A \& B \& S[31]);$
 // note: S is the output of the adder

When the ALU is performing addition, $F[2] = 0$. With subtraction, $F[2] =$
 1. Thus,

$\text{Overflow} = \sim F[2] \& (A \& B \& \sim S[31] \mid \sim A \& \sim B \& S[31]) \mid$
 $F[2] \& (\sim A \& B \& S[31] \mid A \& \sim B \& \sim S[31]);$

(b)

        end case;
    end process;
end;
```

Exercise 5.15

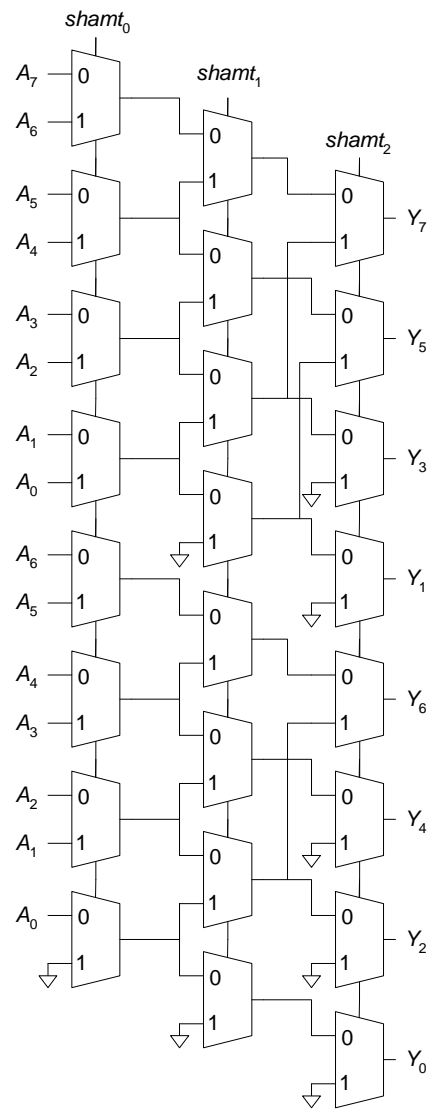

FIGURE 5.7 8-bit left shifter using 24 2:1 multiplexers

Exercise 5.16

Any N -bit shifter can be built by using $\log_2 N$ columns of 2-bit shifters. The first column of multiplexers shifts or rotates 0 to 1 bit, the second column shifts or rotates 0 to 3 bits, the following 0 to 7 bits, etc. until the final column shifts or rotates 0 to $N-1$ bits. The second column of multiplexers takes its inputs from the first column of multiplexers, the third column takes its input from the second column, and so forth. The 1-bit select input of each column is a single bit of the *shamt* (shift amount) control signal, with the least significant bit for the left-most column and the most significant bit for the right-most column.

Exercise 5.17

- (a) $B = 0, C = A, k = \text{shamt}$
- (b) $B = A_{N-1}$ (the most significant bit of A), repeated N times to fill all N bits of B
- (c) $B = A, C = 0, k = N - \text{shamt}$
- (d) $B = A, C = A, k = \text{shamt}$
- (e) $B = A, C = A, k = N - \text{shamt}$

Exercise 5.18

$$t_{pd_MULT4} = t_{AND} + 8t_{FA}$$

For $N = 1$, the delay is t_{AND} . For $N > 1$, an $N \times N$ multiplier has N -bit operands, N partial products, and $N-1$ stages of 1-bit adders. The delay is through the AND gate, then through all N adders in the first stage, and finally through 2 adder delays for each of the remaining stages. So the propagation is:

$$t_{pd_MULTN} = t_{AND} + [N + 2(N-2)]t_{FA}$$

Exercise 5.19

$$t_{pd_DIV4} = 4(4t_{FA} + t_{MUX}) = 16t_{FA} + 4t_{MUX}$$

$$t_{pd_DIVN} = N^2 t_{FA} + N t_{MUX}$$

Exercise 5.20

Recall that a two's complement number has the same weights for the least significant $N-1$ bits, regardless of the sign. The sign bit has a weight of -2^{N-1} . Thus, the product of two N -bit complement numbers, y and x is:

$$P = \left(-y_{N-1}2^{N-1} + \sum_{j=0}^{N-2} y_j2^j \right) \left(-x_{N-1}2^{N-1} + \sum_{i=0}^{N-2} x_i2^i \right)$$

Thus,

$$\sum_{i=0}^{N-2} \sum_{j=0}^{N-2} x_i y_j 2^{i+j} + x_{N-1} y_{N-1} 2^{2N-2} - \sum_{i=0}^{N-2} x_i y_{N-1} 2^{i+N-1} - \sum_{j=0}^{N-2} x_{N-1} y_j 2^{j+N-1}$$

The two negative partial products are formed by taking the two's complement (inverting the bits and adding 1). Figure 5.8 shows a 4 x 4 multiplier. Figure 5.8 (b) shows the partial products using the above equation. Figure 5.8 (c) shows a simplified version, pushing through the 1's. This is known as a *modified Baugh-Wooley multiplier*. It can be built using a hierarchy of adders.

begin
    y <= "0000" & a(3 downto 0);
end;
```

Exercise 5.23

$$\begin{array}{r}
 100.110 \\
 1100 \overline{) 111001.000} \\
 \underline{-1100} \\
 00100 \\
 \underline{-1100} \\
 1100 \\
 \underline{-1100} \\
 0
 \end{array}$$

Exercise 5.24

$$\begin{aligned} \text{(a)} \quad & \left[0, \left(2^{12} - 1 + \frac{2^{12} - 1}{2^{12}} \right) \right] \\ \text{(b)} \quad & \left[- \left(2^{11} - 1 + \frac{2^{12} - 1}{2^{12}} \right), \left(2^{11} - 1 + \frac{2^{12} - 1}{2^{12}} \right) \right] \\ \text{(c)} \quad & \left[- \left(2^{11} + \frac{2^{12} - 1}{2^{12}} \right), \left(2^{11} - 1 + \frac{2^{12} - 1}{2^{12}} \right) \right] \end{aligned}$$

Exercise 5.25

- (a) $1000\ 1101\ .\ 1001\ 0000 = 0x8D90$
- (b) $0010\ 1010\ .\ 0101\ 0000 = 0x2A50$
- (c) $1001\ 0001\ .\ 0010\ 1000 = 0x9128$

Exercise 5.26

- (a) $111110.100000 = 0xFA0$
- (b) $010000.010000 = 0x410$
- (c) $101000.000101 = 0xA05$

Exercise 5.27

- (a) $1111\ 0010\ .\ 0111\ 0000 = 0xF270$
- (b) $0010\ 1010\ .\ 0101\ 0000 = 0x2A50$
- (c) $1110\ 1110\ .\ 1101\ 1000 = 0xEED8$

Exercise 5.28

- (a) $100001.100000 = 0x860$
- (b) $010000.010000 = 0x410$
- (c) $110111.111011 = 0xDFB$

Exercise 5.29

- (a) $-1101.1001 = -1.1011001 \times 2^3$
Thus, the biased exponent $= 127 + 3 = 130 = 1000\ 0010_2$
In IEEE 754 single-precision floating-point format:
 $1\ 1000\ 0010\ 101\ 1001\ 0000\ 0000\ 0000\ 0000 = \mathbf{0xC1590000}$
- (b) $101010.0101 = 1.010100101 \times 2^5$
Thus, the biased exponent $= 127 + 5 = 132 = 1000\ 0100_2$
In IEEE 754 single-precision floating-point format:
 $0\ 1000\ 0100\ 010\ 1001\ 0100\ 0000\ 0000\ 0000 = \mathbf{0x42294000}$
- (c) $-10001.00101 = -1.000100101 \times 2^4$
Thus, the biased exponent $= 127 + 4 = 131 = 1000\ 0011_2$
In IEEE 754 single-precision floating-point format:
 $1\ 1000\ 0011\ 000\ 1001\ 0100\ 0000\ 0000\ 0000 = \mathbf{0xC1894000}$

Exercise 5.30

(a) $-11110.1 = -1.111101 \times 2^4$

Thus, the biased exponent = $127 + 4 = 131 = 1000\ 0011_2$

In IEEE 754 single-precision floating-point format:

1 1000 0011 111 1010 0000 0000 0000 0000 = **0xC1F40000**

(b) $10000.01 = 1.000001 \times 2^4$

Thus, the biased exponent = $127 + 4 = 131 = 1000\ 0011_2$

In IEEE 754 single-precision floating-point format:

0 1000 0011 000 0010 0100 0000 0000 0000 = **0x41820000**

(c) $-1000.000101 = -1.000000101 \times 2^3$

Thus, the biased exponent = $127 + 3 = 130 = 1000\ 0010_2$

In IEEE 754 single-precision floating-point format:

1 1000 0010 000 0001 0100 0000 0000 0000 = **0xC1014000**

Exercise 5.31

(a) 5.5

(b) $-0000.0001_2 = -0.0625$

(c) -8

Exercise 5.32

(a) 29.65625

(b) -25.1875

(c) -23.875

Exercise 5.33

When adding two floating point numbers, the number with the smaller exponent is shifted to preserve the most significant bits. For example, suppose we were adding the two floating point numbers 1.0×2^0 and 1.0×2^{-27} . We make the two exponents equal by shifting the second number right by 27 bits. Because the mantissa is limited to 24 bits, the second number ($1.000\ 0000\ 0000\ 0000\ 0000 \times 2^{-27}$) becomes $0.000\ 0000\ 0000\ 0000\ 0000 \times 2^0$, because the 1 is shifted off to the right. If we had shifted the number with the larger exponent (1.0×2^0) to the left, we would have shifted off the more significant bits (on the order of 2^0 instead of on the order of 2^{-27}).

Exercise 5.34

- (a) C0123456
- (b) D1E072C3
- (c) 5F19659A

Exercise 5.35

- (a)
- $$\begin{aligned} 0xC0D20004 &= 1\ 1000\ 0001\ 101\ 0010\ 0000\ 0000\ 0000\ 0100 \\ &= -1.101\ 0010\ 0000\ 0000\ 0000\ 01 \times 2^2 \\ 0x72407020 &= 0\ 1110\ 0100\ 100\ 0000\ 0111\ 0000\ 0010\ 0000 \\ &= 1.100\ 0000\ 0111\ 0000\ 001 \times 2^{101} \end{aligned}$$

When adding these two numbers together, 0xC0D20004 becomes:
 0×2^{101} because all of the significant bits shift off the right when making the exponents equal. Thus, the result of the addition is simply the second number:

0x72407020

- (b)
- $$\begin{aligned} 0xC0D20004 &= 1\ 1000\ 0001\ 101\ 0010\ 0000\ 0000\ 0000\ 0100 \\ &= -1.101\ 0010\ 0000\ 0000\ 0000\ 01 \times 2^2 \\ 0x40DC0004 &= 0\ 1000\ 0001\ 101\ 1100\ 0000\ 0000\ 0000\ 0100 \\ &= 1.101\ 1100\ 0000\ 0000\ 0000\ 01 \times 2^2 \end{aligned}$$

$$\begin{aligned} &1.101\ 1100\ 0000\ 0000\ 0000\ 01 \times 2^2 \\ &- 1.101\ 0010\ 0000\ 0000\ 0000\ 01 \times 2^2 \\ &= 0.000\ 1010 \times 2^2 \\ &= 1.010 \times 2^{-2} \\ &= 0\ 0111\ 1101\ 010\ 0000\ 0000\ 0000\ 0000\ 0000 \\ &= 0x3EA00000 \end{aligned}$$

- (c)
- $$\begin{aligned} 0x5FBE4000 &= 0\ 1011\ 1111\ 011\ 1110\ 0100\ 0000\ 0000\ 0000\ 0000 \\ &= 1.011\ 1110\ 01 \times 2^{64} \\ 0x3FF80000 &= 0\ 0111\ 1111\ 111\ 1000\ 0000\ 0000\ 0000\ 0000 \\ &= 1.111\ 1 \times 2^0 \\ 0xDFDE4000 &= 1\ 1011\ 1111\ 101\ 1110\ 0100\ 0000\ 0000\ 0000\ 0000 \\ &= -1.101\ 1110\ 01 \times 2^{64} \end{aligned}$$

Thus, $(1.011\ 1110\ 01 \times 2^{64} + 1.111\ 1 \times 2^0) = 1.011\ 1110\ 01 \times 2^{64}$

And, $(1.011\ 1110\ 01 \times 2^{64} + 1.111\ 1 \times 2^0) - 1.101\ 1110\ 01 \times 2^{64} =$
 $- 0.01 \times 2^{64} = -1.0 \times 2^{64}$
 $= 1\ 1011\ 1101\ 000\ 0000\ 0000\ 0000\ 0000\ 0000$
 $= \mathbf{0xDE800000}$

This is counterintuitive because the second number (0x3FF80000) does not affect the result because its order of magnitude is less than 2^{23} of the other numbers. This second number's significant bits are shifted off when the exponents are made equal.

Exercise 5.36

We only need to change step 5.

1. Extract exponent and fraction bits.
2. Prepend leading 1 to form the mantissa.
3. Compare exponents.
4. Shift smaller mantissa if necessary.
5. If one number is negative: Subtract it from the other number. If the result is negative, take the absolute value of the result and make the sign bit 1.

If both numbers are negative: Add the numbers and make the sign bit 1.

If both numbers are positive: Add the numbers and make the sign bit 0.

6. Normalize mantissa and adjust exponent if necessary.
7. Round result
8. Assemble exponent and fraction back into floating-point number

Exercise 5.37

(a) $2(2^{31} - 1 - 2^{23}) = 2^{32} - 2 - 2^{24} = 4,278,190,078$

(b) $2(2^{31} - 1) = 2^{32} - 2 = 4,294,967,294$

(c) $\pm\infty$ and NaN are given special representations because they are often used in calculations and in representing results. These values also give useful information to the user as return values, instead of returning garbage upon overflow, underflow, or divide by zero.

Exercise 5.38

$$\begin{aligned} \text{(a) } 245 &= 11110101 = 1.1110101 \times 2^7 \\ &= 0\ 1000\ 0110\ 111\ 0101\ 0000\ 0000\ 0000\ 0000 \\ &= 0x43750000 \\ 0.0625 &= 0.0001 = 1.0 \times 2^{-4} \\ &= 0\ 0111\ 1011\ 000\ 0000\ 0000\ 0000\ 0000\ 0000 \\ &= 0x3D800000 \end{aligned}$$

(b) 0x43750000 is greater than 0x3D800000, so magnitude comparison gives the correct result.

$$\begin{aligned} \text{(c)} \\ 1.1110101 \times 2^7 &= 0\ 0000\ 0111\ 111\ 0101\ 0000\ 0000\ 0000\ 0000 \\ &= 0x03F50000 \\ 1.0 \times 2^{-4} &= 0\ 1111\ 1100\ 000\ 0000\ 0000\ 0000\ 0000\ 0000 \\ &= 0x7E000000 \end{aligned}$$

(d) No, integer comparison no longer works. $7E000000 > 03F50000$ (indicating that 1.0×2^{-4} is greater than 1.1110101×2^7 , which is incorrect.)

(e) It is convenient for integer comparison to work with floating-point numbers because then the computer can compare numbers without needing to extract the mantissa, exponent, and sign.

Exercise 5.39

Exercise 5.40

(a)

- Extract exponent and fraction bits.
- Prepend leading 1 to form the mantissa.
- Add exponents.
- Multiply mantissas.
- Round result and truncate mantissa to 24 bits.
- Assemble exponent and fraction back into floating-point number

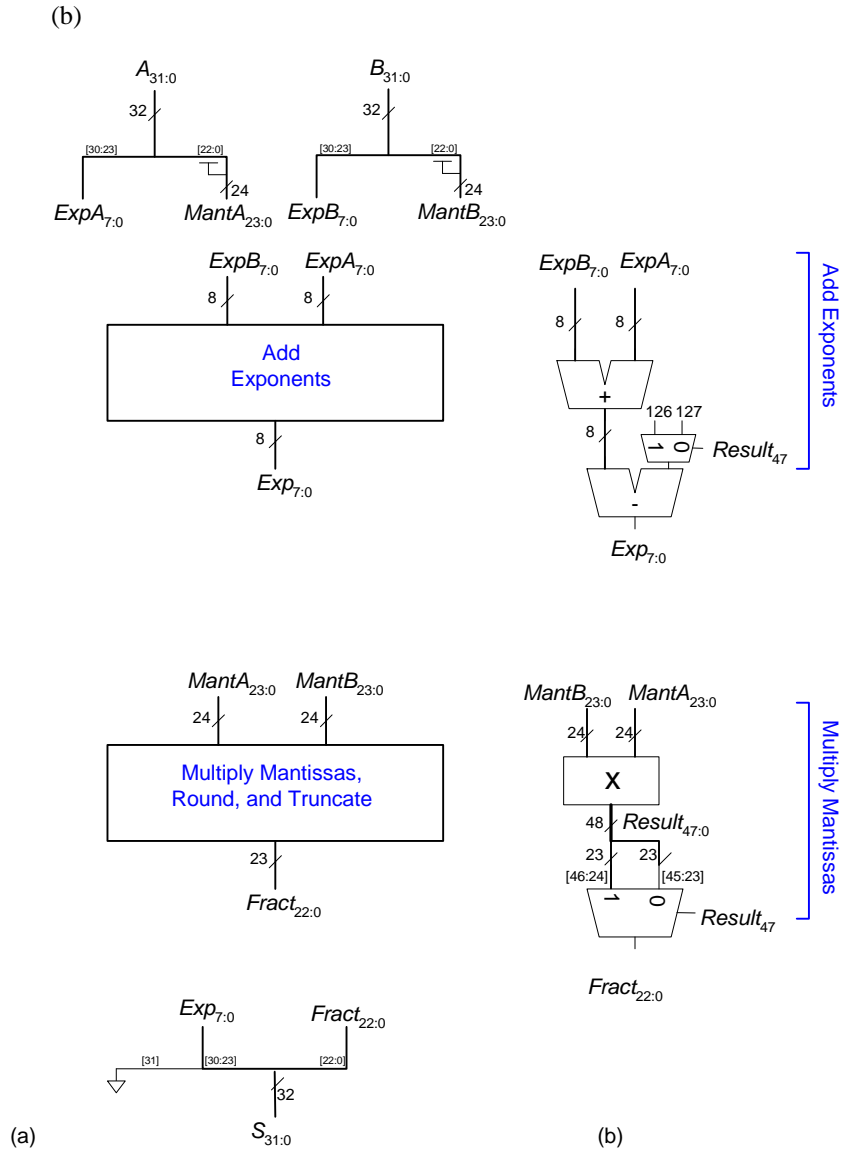

FIGURE 5.12 Floating-point multiplier block diagram

5.41 (c) Using Equation 5.11 to find the delay of the prefix adder:

$$t_{PA} = t_{pg} + \log_2 N(t_{pg_prefix}) + t_{XOR}$$

We find the delays for each block:

$$t_{pg} = 100 \text{ ps}$$

$$t_{pg_prefix} = 200 \text{ ps}$$

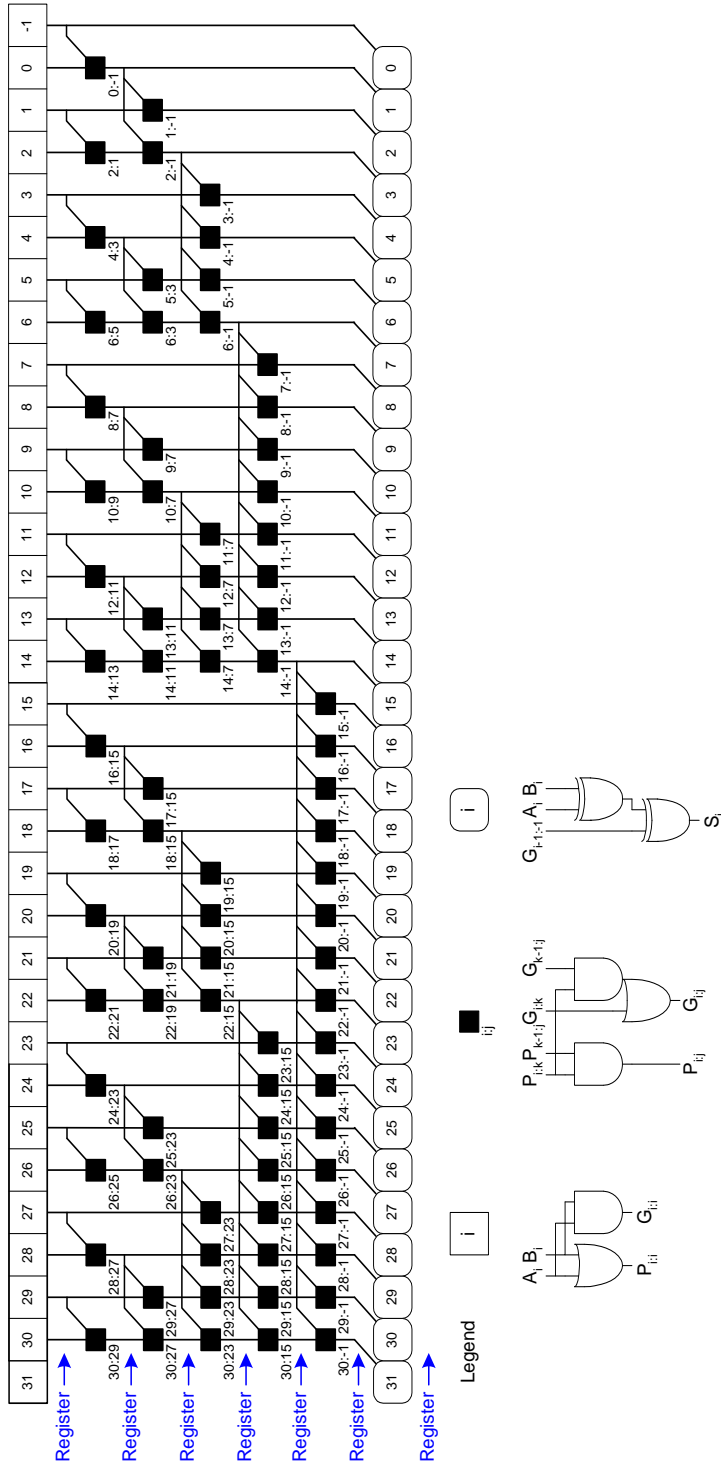

$$t_{XOR} = 100 \text{ ps}$$

Thus,

$$t_{PA} = [100 + 5(200) + 100] \text{ ps} = 1200 \text{ ps} = \mathbf{1.2 \text{ ns}}$$

5.41 (d) To make a pipelined prefix adder, add pipeline registers between each of the rows of the prefix adder. Now each stage will take 200 ps plus the

sequencing overhead, $t_{pq} + t_{\text{setup}} = 80\text{ps}$. Thus each cycle is 280 ps and the design can run at 3.57 GHz.

5.41 (e)

$2N$. 1's shift into the left-most bit for N cycles, then 0's shift into the left bit for N cycles. Then the process repeats.

5.46 (c)

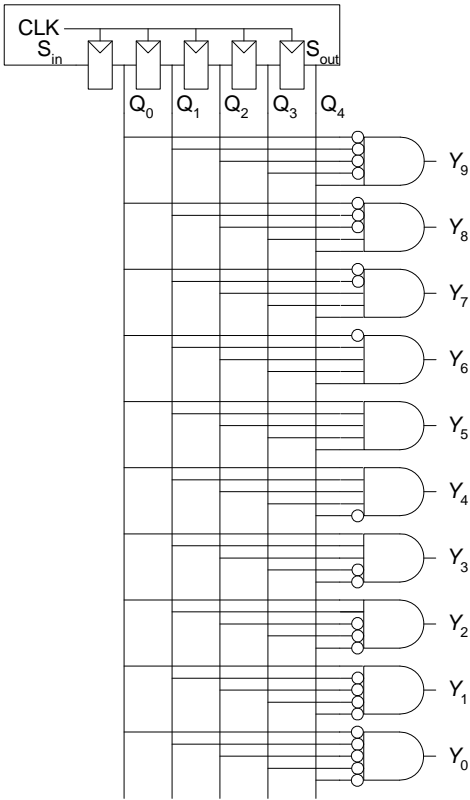

FIGURE 5.17 10-bit decimal counter using a 5-bit Johnson counter

(d) The counter uses less hardware and could be faster because it has a short critical path (a single inverter delay).

Exercise 5.47

SystemVerilog

```
module scanflop4(input logic clk, test, sin,
                 input logic [3:0] d,
                 output logic [3:0] q,
                 output logic sout);

    always_ff @(posedge clk)
        if (test)
            q <= d;
        else
            q <= {q[2:0], sin};

    assign sout = q[3];
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity scanflop4 is
    port(clk, test, sin: in STD_LOGIC;
         d: in STD_LOGIC_VECTOR(3 downto 0);
         q: inout STD_LOGIC_VECTOR(3 downto 0);
         sout: out STD_LOGIC);
end;

architecture synth of scanflop4 is
begin
    process(clk, test) begin
        if rising_edge(clk) then
            if test then
                q <= d;
            else
                q <= q(2 downto 0) & sin;
            end if;
        end if;
    end process;

    sout <= q(3);
end;
```

Exercise 5.48

(a)

value <i>a</i> _{1:0}	encoding <i>y</i> _{4:0}
00	00001
01	01010
10	10100
11	11111

TABLE 5.2 Possible encodings

The first two pairs of bits in the bit encoding repeat the value. The last bit is the XNOR of the two input values.

5.48 (b) This circuit can be built using a 16×2 -bit memory array, with the contents given in Table 5.3.

address <i>a</i> _{4:0}	data <i>d</i> _{1:0}
00001	00
00000	00
00011	00
00101	00

TABLE 5.3 Memory array values for Exercise 5.48

address $a_{4:0}$	data $d_{1:0}$
01111	11
others	XX

TABLE 5.3 Memory array values for Exercise 5.48

5.48 (c) The implementation shown in part (b) allows the encoding to change easily. Each memory address corresponds to an encoding, so simply store different data values at each memory address to change the encoding.

Exercise 5.49

<http://www.intel.com/design/flash/articles/what.htm>

Flash memory is a nonvolatile memory because it retains its contents after power is turned off. Flash memory allows the user to electrically program and erase information. Flash memory uses memory cells similar to an EEPROM, but with a much thinner, precisely grown oxide between a floating gate and the substrate (see Figure 5.18).

Flash programming occurs when electrons are placed on the floating gate. This is done by forcing a large voltage (usually 10 to 12 volts) on the control gate. Electrons quantum-mechanically tunnel from the source through the thin oxide onto the control gate. Because the floating gate is completely insulated by oxide, the charges are trapped on the floating gate during normal operation. If electrons are stored on the floating gate, it blocks the effect of the control gate. The electrons on the floating gate can be removed by reversing the procedure, i.e., by placing a large negative voltage on the control gate.

The default state of a flash bitcell (when there are no electrons on the floating gate) is ON, because the channel will conduct when the wordline is HIGH. After the bitcell is programmed (i.e., when there are electrons on the floating gate), the state of the bitcell is OFF, because the floating gate blocks the effect of the control gate. Flash memory is a key element in thumb drives, cell phones, digital cameras, Blackberries, and other low-power devices that must retain their memory when turned off.

Exercise 5.50

FIGURE 5.19 4 x 4 x 3 PLA implementing Exercise 5.44

5.50 (b)

FIGURE 5.20 16 x 3 ROM implementation of Exercise 5.44

5.50 (c)

SystemVerilog

```
module ex5_44c(input logic u, b, s, g,
               output logic m, j, v);

    assign m = s&g | u&b&s;
    assign j = ~u&b&~s | s&g;
    assign v = u&b&s | ~u&~s&g;
endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;

entity ex5_44c is
    port(u, b, s, g: in STD_LOGIC;
          m, j, v: out STD_LOGIC);
end;

architecture synth of ex5_44c is
begin
    m <= (s and g) or (u and b and s);
    j <= ((not u) and b and (not s)) or (s and g);
    v <= (u and b and s) or ((not u) and (not s) and g);
end;
```

Exercise 5.51

Exercise 5.52

FIGURE 5.21 4 x 8 x 3 PLA for Exercise 5.52

Exercise 5.53

- (a) Number of inputs = $2 \times 16 + 1 = 33$
Number of outputs = $16 + 1 = 17$

Thus, this would require a $2^{33} \times 17$ -bit ROM.

- (b) Number of inputs = 16
Number of outputs = 16

Thus, this would require a $2^{16} \times 16$ -bit ROM.

- (c) Number of inputs = 16
Number of outputs = 4

Thus, this would require a 2^{16} x 4-bit ROM.

All of these implementations are not good design choices. They could all be implemented in a smaller amount of hardware using discrete gates.

Exercise 5.54

- (a) Yes. Both circuits can compute any function of K inputs and K outputs.
- (b) No. The second circuit can only represent 2^K states. The first can represent more.
- (c) Yes. Both circuits compute any function of 1 input, N outputs, and 2^K states.
- (d) No. The second circuit forces the output to be the same as the state encoding, while the first one allows outputs to be independent of the state encoding.

LE 3

Exercise 5.57

(a) 5 LEs (2 for next state logic and state registers, 3 for output logic)

(b)

$$\begin{aligned} t_{pd} &= t_{pd_LE} + t_{wire} \\ &= (381 + 246) \text{ ps} \\ &= 627 \text{ ps} \end{aligned}$$

$$\begin{aligned} T_c &\geq t_{pcq} + t_{pd} + t_{setup} \\ &\geq [199 + 627 + 76] \text{ ps} \\ &= 902 \text{ ps} \end{aligned}$$

$$f = 1 / 902 \text{ ps} = \mathbf{1.1 \text{ GHz}}$$

(c)

First, we check that there is no hold time violation with this amount of clock skew.

$$\begin{aligned} t_{cd_LE} &= t_{pd_LE} = 381 \text{ ps} \\ t_{cd} &= t_{cd_LE} + t_{wire} = 627 \text{ ps} \end{aligned}$$

$$\begin{aligned} t_{skew} &< (t_{ccq} + t_{cd}) - t_{hold} \\ &< [(199 + 627) - 0] \text{ ps} \\ &< \mathbf{826 \text{ ps}} \end{aligned}$$

3 ns is less than 826 ps, so there is no hold time violation.

Now we find the fastest frequency at which it can run.

$$\begin{aligned} T_c &\geq t_{pcq} + t_{pd} + t_{setup} + t_{skew} \\ &\geq [0.902 + 3] \text{ ns} \\ &= 3.902 \text{ ns} \end{aligned}$$

$$f = 1 / 3.902 \text{ ns} = \mathbf{256 \text{ MHz}}$$

Exercise 5.58

(a) 2 LEs (1 for next state logic and state register, 1 for output logic)

(b) Same as answer for Exercise 5.57(b)

(c) Same as answer for Exercise 5.57(c)

Exercise 5.59

First, we find the cycle time:

$$T_c = 1/f = 1/100 \text{ MHz} = 10 \text{ ns}$$

$$\begin{aligned} T_c &\geq t_{pcq} + N t_{LE+wire} + t_{setup} \\ 10 \text{ ns} &\geq [0.199 + N(0.627) + 0.076] \text{ ns} \end{aligned}$$

Thus, $N \leq 15.5$

The maximum number of LEs on the critical path is **15**.

With at most one LE on the critical path and no clock skew, the fastest the FSM will run is:

$$\begin{aligned} T_c &\geq [0.199 + 0.627 + 0.076] \text{ ns} \\ &\geq 0.902 \text{ ns} \\ f &= 1 / 0.902 \text{ ns} = \mathbf{1.1 \text{ GHz}} \end{aligned}$$

Question 5.1

$$(2^N - 1)(2^N - 1) = 2^{2N} - 2^{N+1} + 1$$

Question 5.2

A processor might use BCD representation so that decimal numbers, such as 1.7, can be represented exactly.

Question 5.3

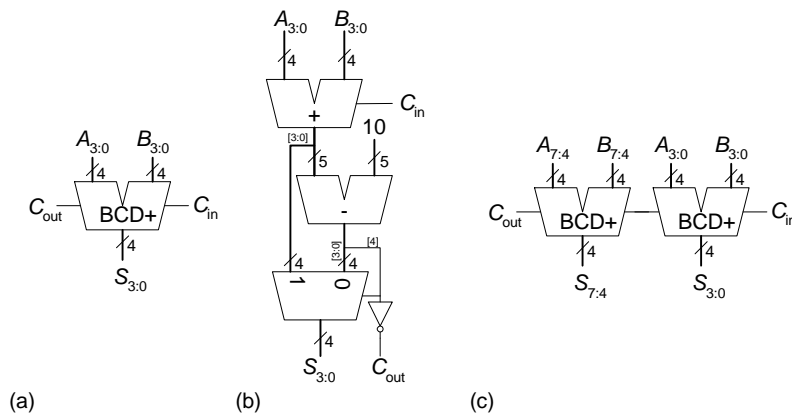

FIGURE 5.22 BCD adder: (a) 4-bit block, (b) underlying hardware, (c) 8-bit BCD adder

end;
```

CHAPTER 6

Exercise 6.1

(1) Simplicity favors regularity:

- Each instruction has a 6-bit opcode.
- MIPS has only 3 instruction formats (R-Type, I-Type, J-Type).
- Each instruction format has the same number and order of operands (they differ only in the opcode).
- Each instruction is the same size, making decoding hardware simple.

(2) Make the common case fast.

- Registers make the access to most recently accessed variables fast.
- The RISC (reduced instruction set computer) architecture, makes the common/simple instructions fast because the computer must handle only a small number of simple instructions.
- Most instructions require all 32 bits of an instruction, so all instructions are 32 bits (even though some would have an advantage of a larger instruction size and others a smaller instruction size). The instruction size is chosen to make the common instructions fast.

(3) Smaller is faster.

- The register file has only 32 registers.

- The ISA (instruction set architecture) includes only a small number of commonly used instructions. This keeps the hardware small and, thus, fast.
 - The instruction size is kept small to make instruction fetch fast.
- (4) Good design demands good compromises.
- MIPS uses three instruction formats (instead of just one).
 - Ideally all accesses would be as fast as a register access, but MIPS architecture also supports main memory accesses to allow for a compromise between fast access time and a large amount of memory.
 - Because MIPS is a RISC architecture, it includes only a set of simple instructions, it provides pseudocode to the user and compiler for commonly used operations, like moving data from one register to another (`move`) and loading a 32-bit immediate (`li`).

Exercise 6.2

Yes, it is possible to design a computer architecture without a register set. For example, an architecture could use memory as a very large register set. Each instruction would require a memory access. For example, an add instruction might look like this:

```
add 0x10, 0x20, 0x24
```

This would add the values stored at memory addresses 0x20 and 0x24 and place the result in memory address 0x10. Other instructions would follow the same pattern, accessing memory instead of registers. Some advantages of the architecture are that it would require fewer instructions. Load and store operations are now unnecessary. This would make the decoding hardware simpler and faster.

Some disadvantages of this architecture over the MIPS architecture is that each operation would require a memory access. Thus, either the processor would need to be slow or the memory small. Also, because the instructions must encode memory addresses instead of register numbers, the instruction size would be large in order to access all memory addresses. Or, alternatively, each instruction can only access a smaller number of memory addresses. For example, the architecture might require that one of the source operands is also a destination operand, reducing the number of memory addresses that must be encoded.

Exercise 6.3

- (a) $42 \times 4 = 42 \times 2^2 = 101010_2 \ll 2 = 10101000_2 = 0xA8$
(b) 0xA8 through 0xAB
(c)

Exercise 6.4

- (a) $15 \times 4 = 42 \times 2^2 = 1111_2 \ll 2 = 111100_2 = 0x3C$
(b) 0x3C through 0x3F
(c)

Exercise 6.5

```
# Big-endian
li    $t0, 0xABCD9876
sw    $t0, 100($0)
lb    $s5, 101($0) # the LSB of $s5 = 0xCD

# Little-endian
li    $t0, 0xABCD9876
sw    $t0, 100($0)
lb    $s5, 101($0) # the LSB of $s5 = 0x98
```

In big-endian format, the bytes are numbered from 100 to 103 from left to right. In little-endian format, the bytes are numbered from 100 to 103 from right to left. Thus, the final load byte (lb) instruction returns a different value depending on the endianness of the machine.

Exercise 6.6

- (a) 0x53 4F 53 00
(b) 0x43 6F 6F 6C 21 00

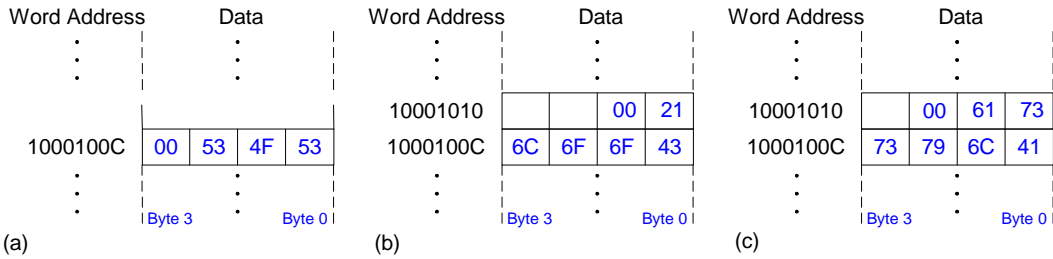

(c) 0x41 6C 79 73 73 61 00 (depends on the persons name)

Exercise 6.7

- (a) 0x68 6F 77 64 79 00
- (b) 0x6C 69 6F 6E 73 00
- (c) 0x54 6F 20 74 68 65 20 72 65 73 63 75 65 21 00

Exercise 6.8

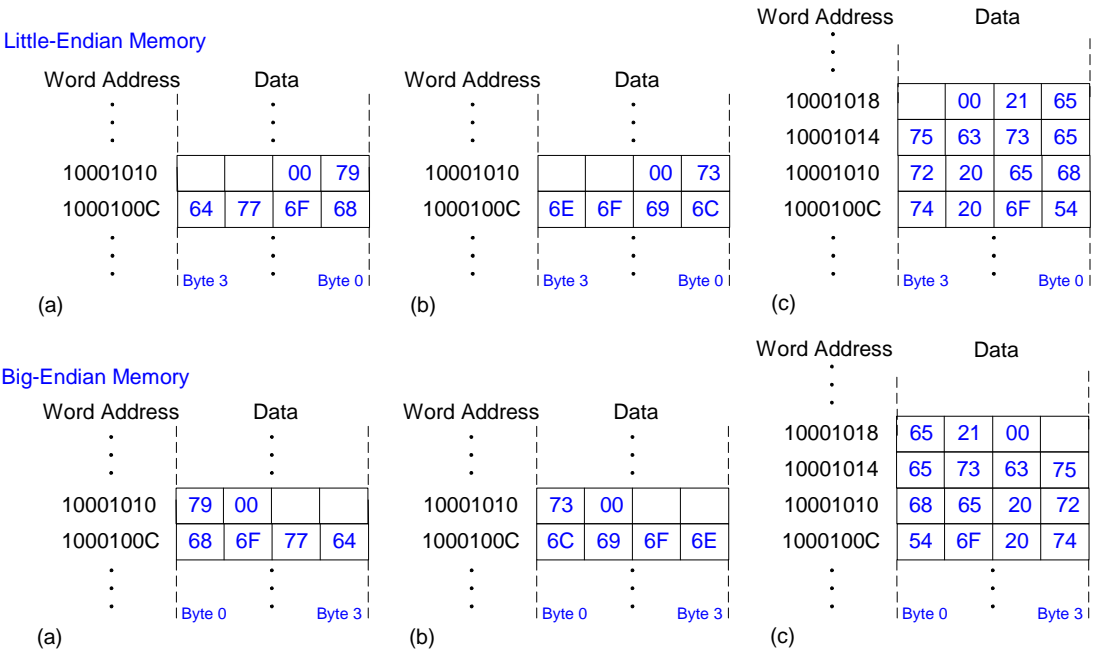

Little-Endian Memory

Big-Endian Memory

Exercise 6.9

Exercise 6.10

0x02114020
0x8de80020
0x2010fff6

Exercise 6.11

0x20100049
0xad49fff9
0x02f24822

Exercise 6.12

(a)
lw \$t0, 0x20(\$t7)
addi \$s0, \$0, -10
(b)
0x8de80020 (lw)
0x2010fff6 (addi)

Exercise 6.13

(a)
addi \$s0, \$0, 73
sw \$t1, -7(\$t2)

(b)
0x20100049 (addi)
0xad49fff9 (sw)

Exercise 6.14

The program is:

[0x00400000]	0x20080000		addi \$t0, \$0, 0
[0x00400004]	0x20090001		addi \$t1, \$0, 1
[0x00400008]	0x0089502a	loop:	slt \$t2, \$a0, \$t1
[0x0040000c]	0x15400003		bne \$t2, \$0, finish
[0x00400010]	0x01094020		add \$t0, \$t0, \$t1
[0x00400014]	0x21290002		addi \$t1, \$t1, 2
[0x00400018]	0x08100002		j loop
[0x0040001c]	0x01001020	finish:	add \$v0, \$t0, \$0

An equivalent C program would be (assuming temp = \$t0, i = \$t1, n = \$a0, result = \$v0):

```
temp = 0;
for (i = 1; i <= n; i = i+2)
    temp = temp + i;

result = temp;
```

This program sums the odd integers up to n and places the result in the return register, \$v0.

Exercise 6.15

```
addi $t0, $0, 31
L1:
srlv $t1, $a0, $t0
andi $t1, $t1, 1
slt $t1, $0, $t1
```

```

sb $t1, 0($a1)
addi $a1, $a1, 1
addi $t0, $t0, -1
bgez $t0, L1
jr $ra

```

(a) This program converts a number (\$a0) from decimal to binary and stores it in an array pointed to by \$a1.

```

void convert2bin(int num, char binarray[])
{
    int i;
    char tmp, val = 31;

    for (i=0; i<32; i++) {
        tmp = (num >> val) & 1;
        binarray[i] = tmp;
        val--;
    }
}

```

Exercise 6.16

```

ori $t0, $t1, 0xF234
nor $t0, $t0, $0

```

Exercise 6.17

```

(a)
# $s0=g, $s1=h
slt $t0, $s1, $s0      # if h < g, $t0 = 1
beq $t0, $0, else      # if $t0 == 0, do else
add $s0, $s0, $s1      # g = g + h
j done                 # jump past else block
else:sub $s0, $s0, $s1  # g = g - h
done:

```

```

(b)
slt $t0, $s0, $s1 # if g < h, $t0 = 1
bne $t0, $0, else # if $t0 != 0, do else
addi $s0, $s0, 1  # g = g + 1
j done           # jump past else block
else: addi $s1, $s1, -1 # h = h - 1
done:

```

```
(c)
slt $t0, $s1, $s0 # if h < g, $t0 = 1
bne $t0, $0, else # if $t0 != 0, do else
add $s0, $0, $0   # g = 0
j  done           # jump past else block
else:  sub $s1, $0, $0 # h = 0
done:
```

Exercise 6.18

```
int find42( int array[], int size)
{
    int i;        // index into array

    for (i = 0; i < size; i = i+1)
        if (array[i] == 42)
            return i;

    return -1;
}
```

Exercise 6.19

```
(a)
# MIPS assembly code
# base address of array dst = $a0
# base address of array src = $a1
# i = $s0

strcpy:
    addi $sp, $sp, -4
    sw   $s0, 0($sp) # save $s0 on the stack
    add  $s0, $0, $0 # i = 0

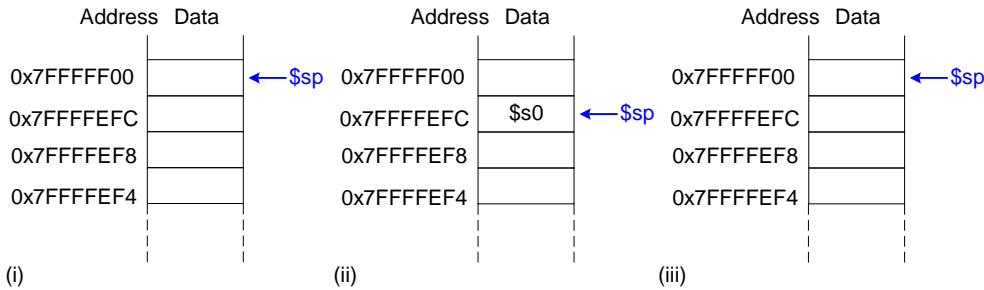

loop:
    add  $t1, $a1, $s0 # $t1 = address of src[i]
    lb   $t2, 0($t1)   # $t2 = src[i]
    add  $t3, $a0, $s0 # $t3 = address of dst[i]
    sb   $t2, 0($t3)   # dst[i] = src[i]
    beq  $t2, $0, done # check for null character
```

```
addi $s0, $s0, 1    # i++
j     loop

done:
    lw  $s0, 0($sp)   # restore $s0 from stack
    addi $sp, $sp, 4  # restore stack pointer
    jr  $ra           # return
```

(b) The stack (i) before, (ii) during, and (iii) after the strcpy procedure call.

Exercise 6.20

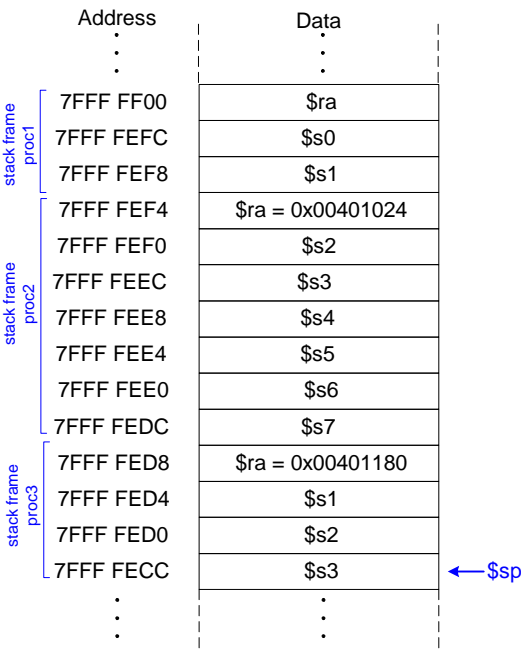

```
find42: addi $t0, $0, 0    # $t0 = i = 0
        addi $t1, $0, 42   # $t1 = 42
loop:   slt  $t3, $t0, $a1  # $t3 = 1 if i < size (not at end of array)
        beq  $t3, $0, exit  # if reached end of array, return -1
        sll  $t2, $t0, 2    # $t2 = i*4
        add  $t2, $t2, $a0  # $t2 = address of array[i]
        lw   $t2, 0($t2)    # $t2 = array[i]
        beq  $t2, $t1, done # $t2 == 42?
        addi $t0, $t0, 1    # i = i + 1
        j    loop
done:   add  $v0, $t0, $0    # $v0 = i
        jr   $ra
exit:   addi $v0, $0, -1    # $v0 = -1
        jr   $ra
```

Exercise 6.21

(a) The stack frames of each procedure are:
proc1: 3 words deep (for \$s0 - \$s1, \$ra)
proc2: 7 words deep (for \$s2 - \$s7, \$ra)
proc3: 4 words deep (for \$s1 - \$s3, \$ra)

proc4: 0 words deep (doesn't use any saved registers or call other procedures)

(b) Note: we arbitrarily chose to make the initial value of the stack pointer 0x7FFFFFF04 just before the procedure calls.

Exercise 6.22

(a)
fib(0) = 0
fib(-1) = 1

```
(b)
int fib(int n)
{
    int prevresult = 1;           // fib(n-1)
    int result = 0;               // fib(n)

    while (n != 0) {              // calculate new fibonacci number
        result = result + prevresult; // fib(n) = fib(n-1) + fib(n-2)
        prevresult = result - prevresult; // fib(n-1) = fib(n) - fib(n-2)
        n = n - 1;
    }
    return result;
}
```

```
(c)
# fib.asm
# 2/21/07 Sarah Harris (Sarah_Harris@hmc.edu)
#
# The fib() procedure computes the nth Fibonacci number.
# n is passed to fib() in $a0, and fib() returns the result in $v0.

main:  addi $a0,$0,9      # initialize procedure argument: n = 9
       jal  fib          # call fibonacci procedure
       ...              # more code
fib:   addi $t0,$0,1      # $t0 = fib(n-1) = fib(-1) = 1
       addi $t1,$0,0      # $t1 = fib(n) = fib(0) = 0
loop:  beq  $a0,$0, end   # done?
       add  $t1,$t1,$t0    # Compute next Fib #, fib(n)
       sub  $t0,$t1,$t0    # Update fib(n-1)
       addi $a0,$a0,-1     # decrement n
       j    loop          # Repeat
end:   add  $v0,$t1,$0     # Put result in $v0
       jr   $ra           # return result
```

Exercise 6.23

- (a) 120
- (b) 2
- (c)
 - (i) 3 - returned value is 1
 - (ii) 2 (depending on what's stored on the stack frame of the callee's stack)
 - (iii) 4

Exercise 6.24

- (a) \$v0 ends with 19, as desired.
- (b) The program will (2) crash. The jump register instruction (`jr $ra`) at instruction address 0x0040004c will return to the most recent value of `$ra` (0x00400030). It will then repeatedly restore values from the stack and increment the stack pointer. Eventually the stack shrinks beyond the dynamic data segment and the program crashes.
- (c)
 - i: The program will (3) produce an incorrect value in `$v0`. `a` (`$a0`) is not restored, but instead holds the value 3 passed to `f2`. So `f` computes $j + a + f2(b) = 5 + 3 + 3 \cdot 3 = 17$
 - ii: The program will (4) run correctly despite the deleted lines. `b` is not restored, but is never used again.
 - iii: (4) `$s0` is not restored. This could corrupt a calling procedure that depended on `$s0` being saved, but does not directly corrupt the result of `f`.
 - iv: (1) Now `f2` does not move and restore the stack pointer, so values saved to the stack get overwritten. When `f2` tries to return, it always finds `$ra`

pointing to 0x04000078. Therefore, we enter an infinite loop from 0x04000078 to 0x0400008c

v: (3) \$s0 is overwritten with the value 3 in f2 and not restored. Thus, when we return to f1, j=3 instead of the desired 5. So $j + a + f2(b) = 3 + 5 + 3*3 = 17$

vi: (2) As in case iv, \$ra is left pointing to 0x04000078 rather than 0x04000030 when we are all done with the recursion on f2. Therefore, we get in an infinite loop from 0x04000078 to 0x0400008c. However, on each loop \$sp is incremented by 12. Eventually it points to an illegal memory location and the program crashes.

vii: (4) x is not restored in f2 after it recursively calls itself. But x is not used after the recursive call, so the program still produces the correct answer.

Exercise 6.25

- (a) 000100 01000 10001 0000 0000 0000 0010

Exercise 6.27

```
(a)
set_array:  addi $sp,$sp,-52    # move stack pointer
            sw  $ra,48($sp)    # save return address
            sw  $s0,44($sp)    # save $s0
            sw  $s1,40($sp)    # save $s1

            add  $s0,$0,$0      # i = 0
            addi $s1,$0,10      # max iterations = 10
loop:       add  $a1,$s0,$0      # pass i as parameter
            jal  compare        # call compare(num, i)
            sll  $t1,$s0,2       # $t1 = i*4
            add  $t2,$sp,$t1     # $t2 = address of array[i]
            sw   $v0,0($t2)      # array[i] = compare(num, i);
            addi $s0,$s0,1       # i++
            bne  $s0,$s1,loop    # if i<10, goto loop

            lw   $s1,40($sp)     # restore $s1
            lw   $s0,44($sp)     # restore $s0
            lw   $ra,48($sp)     # restore return address
            addi $sp,$sp,52      # restore stack pointer
            jr   $ra            # return to point of call

compare:    addi $sp,$sp,-4      # move stack pointer
            sw   $ra,0($sp)      # save return address on the stack
            jal  subtract        # input parameters already in $a0,$a1
            slt  $v0,$v0,$0       # $v0=1 if sub(a,b) < 0 (return 0)
            slti $v0,$v0,1       # $v0=1 if sub(a,b)>=0, else $v0 = 0
            lw   $ra,0($sp)      # restore return address
            addi $sp,$sp,4       # restore stack pointer
            jr   $ra            # return to point of call

subtract:   sub  $v0,$a0,$a1     # return a-b
            jr   $ra            # return to point of call
```

6.27 (b)

(c) If `$ra` were never stored on the stack, the compare function would return to the instruction after the call to subtract (`slt $v0, $v0, $0`) instead of returning to the `set_array` function. The program would enter an infinite loop in the compare function between `jr $ra` and `slt $v0, $v0, $0`. It would increment the stack during that loop until the stack space was exceeded and the program would likely crash.

Exercise 6.28

(a)

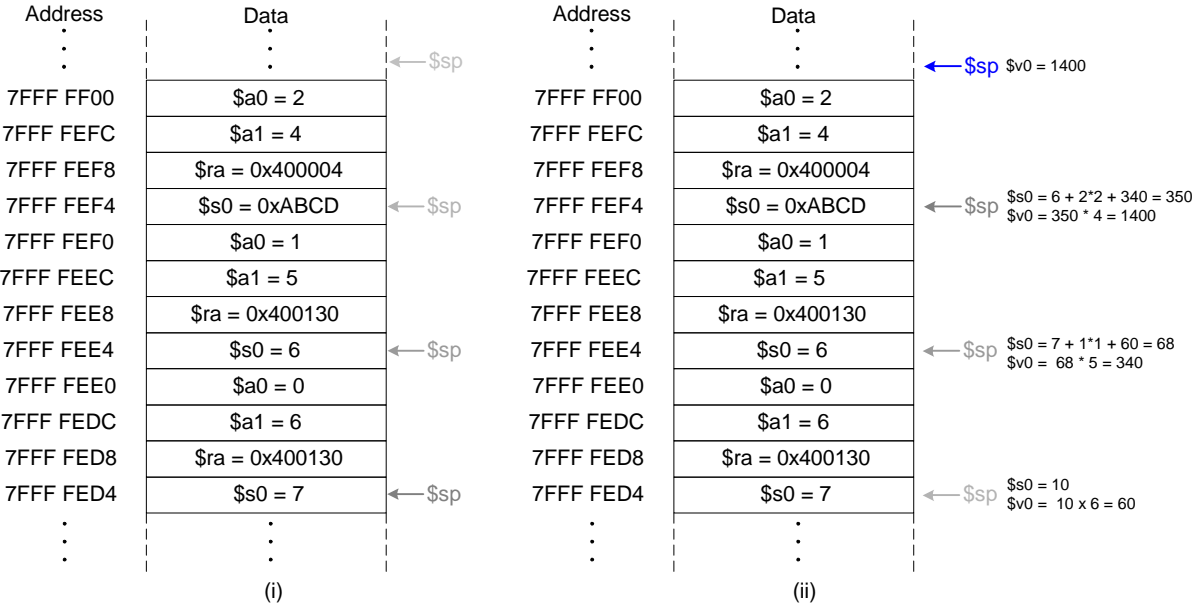

```
# MIPS assembly code
0x400100 f:      addi $sp, $sp, -16 # decrement stack
```

```
0x400104      sw    $a0, 0xc($sp) # save registers on stack
0x400108      sw    $a1, 0x8($sp)
0x40010C      sw    $ra, 0x4($sp)
0x400110      sw    $s0, 0x0($sp)
0x400114      addi  $s0, $a1, 2    # b = k + 2
0x400118      bne  $a0, $0, else   # if (n!=0) do else block
0x40011C      addi  $s0, $0, 10    # b = 10
0x400120      j     done

0x400124 else: addi  $a0, $a0, -1   # update arguments
0x400128      addi  $a1, $a1, 1
0x40012C      jal   f              # call f()
0x400130      lw    $a0, 0xc($sp)  # restore arguments
0x400134      lw    $a1, 0x8($sp)
0x400138      mult  $a0, $a0       # {[hi],[lo]} = n*n
0x40013C      mflo  $t0            # $t0 = lo (assuming 32-bit result)
0x400140      add  $s0, $s0, $t0   # b = b + n*n
0x400144      add  $s0, $s0, $v0   # b = b + n*n + f(n-1,k+1)

0x400148 done: mult  $s0, $a1      # {[hi],[lo]} = b * k
0x40014C      mflo  $v0            # $v0 = lo (assuming 32-bit result)
0x400150      lw    $ra, 0x4($sp)  # restore registers
0x400154      lw    $s0, 0x0($sp)
0x400158      addi  $sp, $sp, 16    # restore stack pointer
0x40015C      jr    $ra           # return
```

6.28 (b) The stack (i) after the last recursive call, and (ii) after return. The final value of `$v0` is 1400.

Exercise 6.29

Instructions (32 K - 1) words before the branch to instructions 32 K words after the branch instruction.

Exercise 6.30

(a) In the worst case, a jump instruction can only jump one instruction forward. For example, the following code is impossible. The jump instruction (`j loop`) below can only jump forward to `0x0FFFFFFC` (at most).

```
0x0FFFFFF8          j    loop
0x0FFFFFFC
0x10000000 loop:    ...
```

(b) In the best case, a jump instruction can jump forward 2^{26} instructions. For example,

```
0x0FFFFFFC          j    loop
0x10000000          ...
0x1FFFFFFC loop:    ...
```

(c)

In the worst case, a jump instruction cannot jump backward. For example, the following code is impossible. Because the jump instruction appends the four most significant bits of `PC + 4`, this jump instruction cannot even jump to itself, let alone further backwards.

```
0x0FFFFFFC loop:    j    loop
0x10000000          ...
```

(d) In the best case, a jump instruction can jump backward at most $2^{26} - 2$ instructions. For example,

```
0x10000000 loop:    ...
...                ...
0x1FFFFFF8          j    loop
```

Exercise 6.31

It is advantageous to have a large address field in the machine format for jump instructions to increase the range of instruction addresses to which the instruction can jump.

Exercise 6.32

```
0x00400000          j Loop1
...
0x0FFFFFFC    Loop1: j Loop2
...
0x10400000    Loop2: ...
```

Another option:

```
0x00400000    lui $t1, 0x1040
0x00400004    jr  $t1
```

Exercise 6.33

```
# high-level code
void little2big(int[] array)
{
    int i;

    for (i = 0; i < 10; i = i + 1) {
        array[i] = ((array[i] << 24) |
                    ((array[i] & 0xFF00) << 8) |
                    ((array[i] & 0xFF0000) >> 8) |
                    ((array[i] >> 24) & 0xFF));
    }
}

# MIPS assembly code
# $a0 = base address of array
little2big:
    addi $t5, $0, 10    # $t5 = i = 10 (loop counter)
loop:   lb  $t0, 0($a0)  # $t0 = array[i] byte 0
        lb  $t1, 1($a0)  # $t1 = array[i] byte 1
        lb  $t2, 2($a0)  # $t2 = array[i] byte 2
        lb  $t3, 3($a0)  # $t3 = array[i] byte 3
        sb  $t3, 0($a0)  # array[i] byte 0 = previous byte 3
        sb  $t2, 1($a0)  # array[i] byte 1 = previous byte 2
        sb  $t1, 2($a0)  # array[i] byte 2 = previous byte 1
        sb  $t0, 3($a0)  # array[i] byte 3 = previous byte 0
        addi $a0, $a0, 4  # increment index into array
        addi $t5, $t5, -1 # decrement loop counter
        beq  $t5, $0, done
        j    loop
done:   jr   $ra
```

Exercise 6.34

(a)

```
void concat(char[] string1, char[] string2, char[] stringconcat)
{
    int i, j;
    i = 0;
    j = 0;

    while (string1[i] != 0) {
        stringconcat[i] = string1[i];
        i = i + 1;
    }
    while (string2[j] != 0) {
        stringconcat[i] = string2[j];
        i = i + 1;
        j = j + 1;
    }
    stringconcat[i] = 0; // append null at end of string
}
```

(b)

```
concat: lb    $t0, 0($a0)      # $t0 = string1[i]
        beq   $t0, $0, string2 # if end of string1, go to string2
        sb    $t0, 0($a2)      # stringconcat[i] = string1[i]
        addi  $a0, $a0, 1      # increment index into string1
        addi  $a2, $a2, 1      # increment index into stringconcat
        j     concat          # loop back
string2: lb    $t0, 0($a1)      # $t0 = string2[j]
        beq   $t0, $0, done     # if end of string2, return
        sb    $t0, 0($a2)      # stringconcat[j] = string2[j]
        addi  $a1, $a1, 1      # increment index into string2
        addi  $a2, $a2, 1      # increment index into stringconcat
        j     string2          # loop back
done:   sb    $0, 0($a2)       # append null to end of string
        jr    $ra
```

Exercise 6.35

```
# define the masks in the global data segment

TABLE 7.15 Adder/subtractor decoder truth table

Exercise 7.7

Before the enhancement (see Equation 7.3, page 380 in the text, also Errata):

$$T_c = t_{pcq_PC} + 2t_{mem} + t_{RFread} + t_{mux} + t_{ALU} + t_{RFsetup}$$
$$= 30 + 2(250) + 150 + 25 + 200 + 20 = \mathbf{925ps}$$

The unit that your friend could speed up that would make the largest reduction in cycle time would be the memory unit. So tmem_new = 125ps, and the new cycle time is:

$$T_c = \mathbf{675\ ps}$$

Exercise 7.8

From Equation 7.3, page 380 in the text (see Errata):

$$T_c = t_{pcq_PC} + 2t_{mem} + t_{RFread} + t_{mux} + t_{ALU} + t_{RFsetup}$$

$$= 30 + 2(250) + 150 + 25 + 180 + 20 = \mathbf{905ps}$$

It would take **90.5 seconds** to execute 100 billion instructions.

Exercise 7.9

- (a) lw
- (b) beq
- (c) beq, j

Exercise 7.10

- (a) R-type, addi
- (b) lw, sw, addi, R-type
- (c) all instructions

Exercise 7.11

SystemVerilog

```

(a) srlv

First, we show the modifications to the ALU.

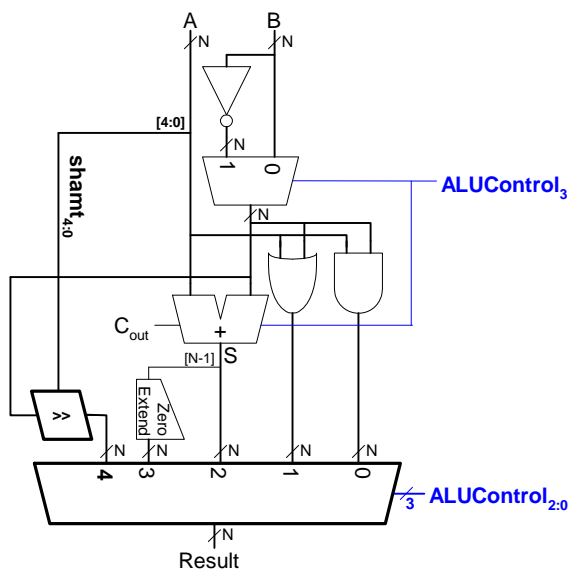

FIGURE 7.11 Modified ALU to support srlv

Next, we show the modifications to the ALU decoder.

ALUControl _{3:0}	Function
0000	A AND B
0001	A OR B
0010	A + B
0011	not used
1000	A AND \overline{B}
1001	A OR \overline{B}
1010	A - B
1011	SLT
0100	SRLV

FIGURE 7.12 Modified ALU operations to support srlv

ALUOp	Funct	ALUControl
00	X	0010 (add)
X1	X	1010 (subtract)
1X	100000 (add)	0010 (add)
1X	100010 (sub)	1010 (subtract)
1X	100100 (and)	0000 (and)
1X	100101 (or)	0001 (or)
1X	101010 (slt)	1011 (set less than)
1X	000110 (srlv)	0100 (shift right logical variable)

TABLE 7.16 ALU decoder truth table

Next, we show the changes to the datapath. The only modification is the width of *ALUControl*. No changes are made to the datapath main control FSM.

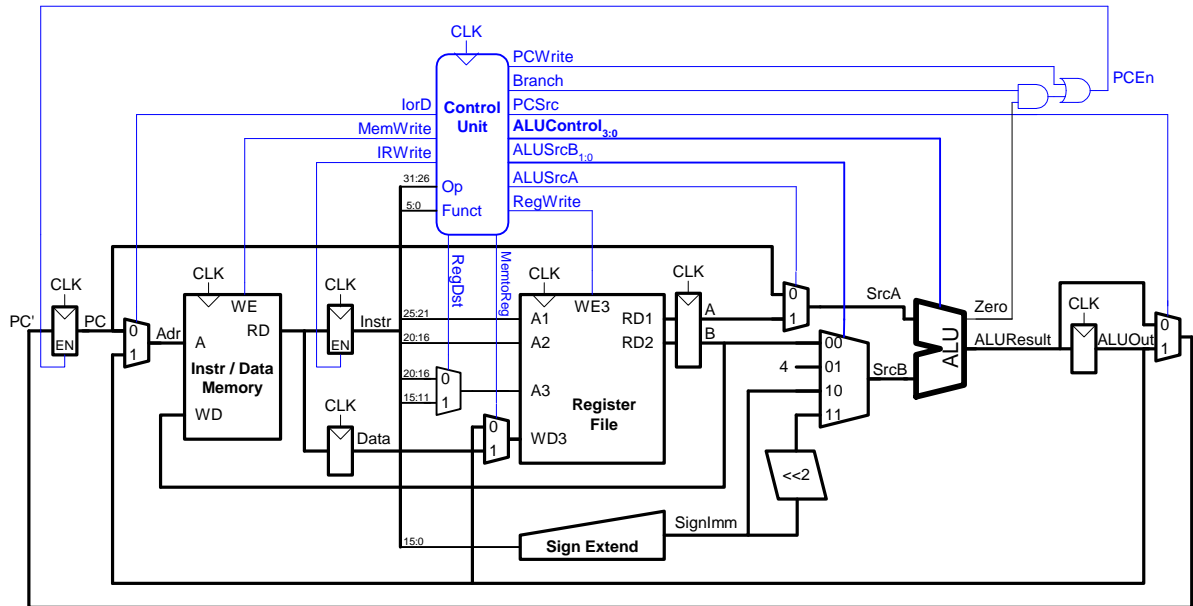

FIGURE 7.13 Modified multicycle MIPS datapath to support `sll`

(b) `ori`

We add a zero extension unit to the datapath, extend the *ALUSrcB* signal from 2 bits to 3 bits, and extend the SrcB multiplexer from 4 inputs to 5 inputs. We also modify the ALU decoder and main control FSM.

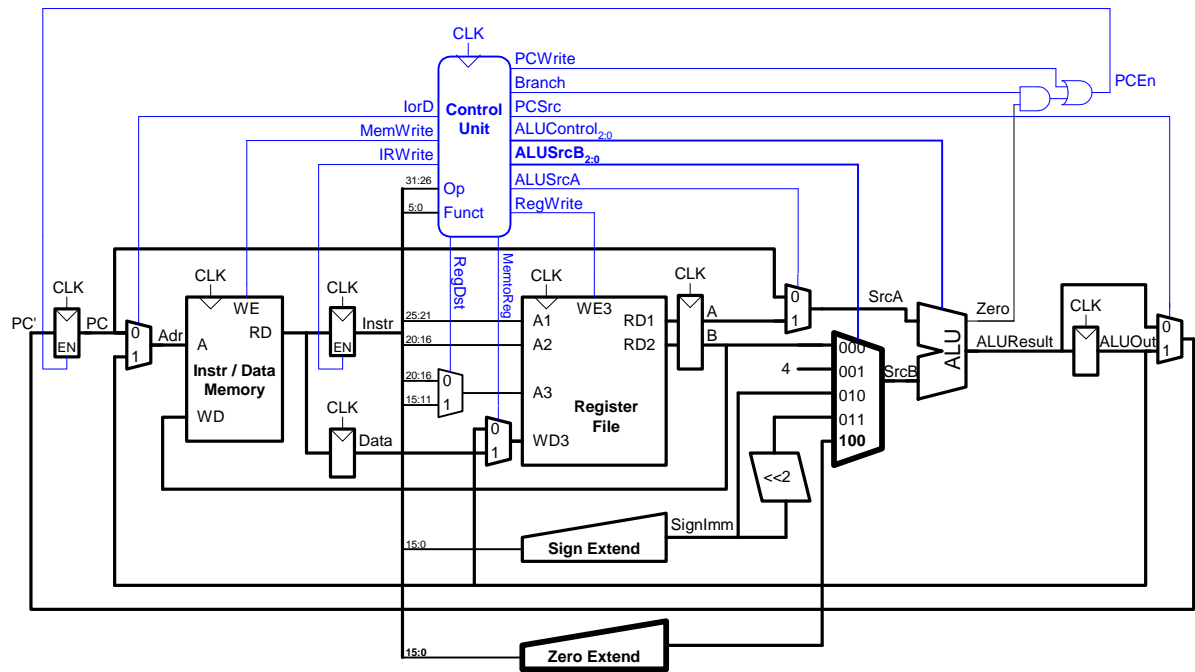

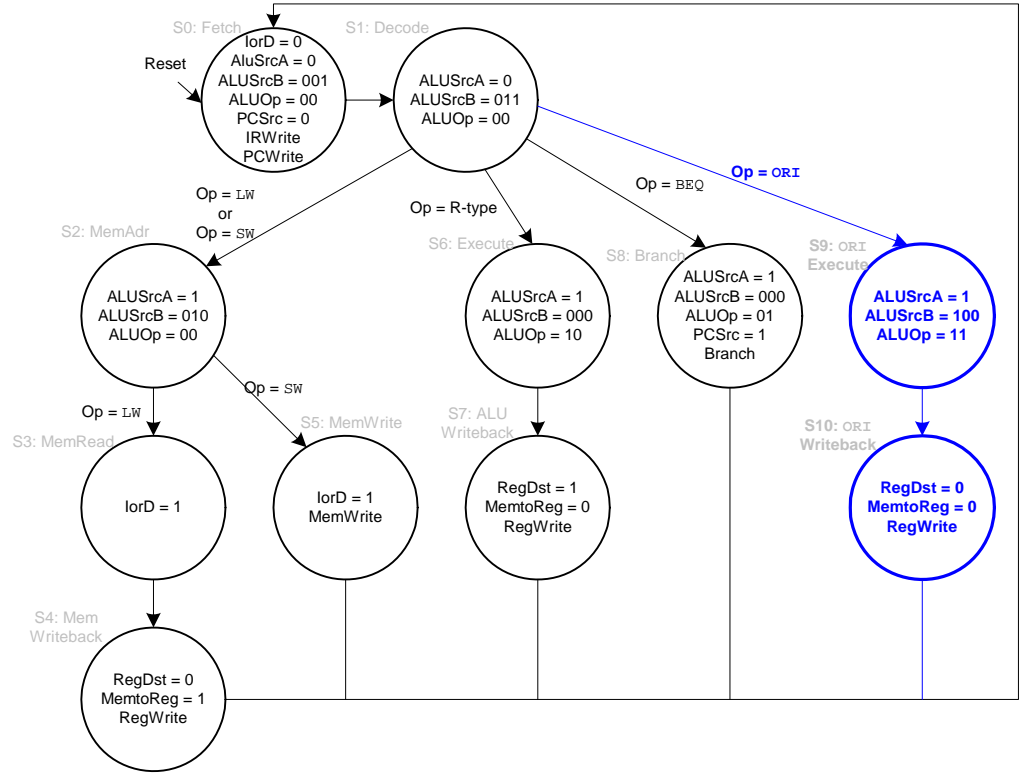

FIGURE 7.14 Modified datapath for *ori*

ALUOp	Funct	ALUControl

10	100000 (add)	010 (add)
10	100010 (sub)	110 (subtract)
10	100100 (and)	000 (and)

TABLE 7.17 ALU decoder truth table

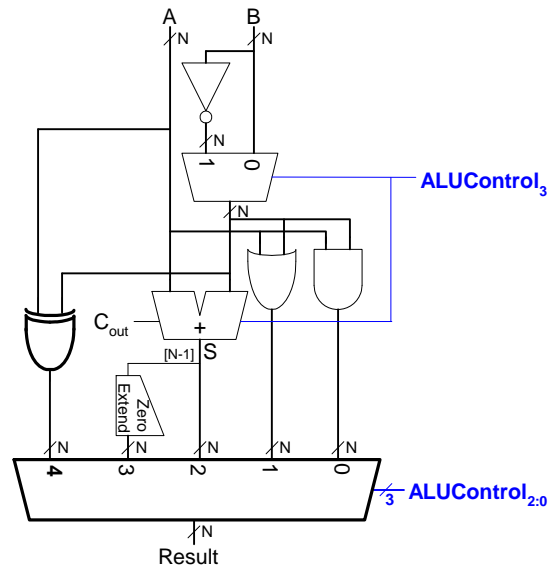

ALUOp	Funct	ALUControl
10	100101 (or)	001 (or)
10	101010 (slt)	111 (set less than)

TABLE 7.17 ALU decoder truth table

(c) xori

First, we modify the ALU and the ALU decoder.

1

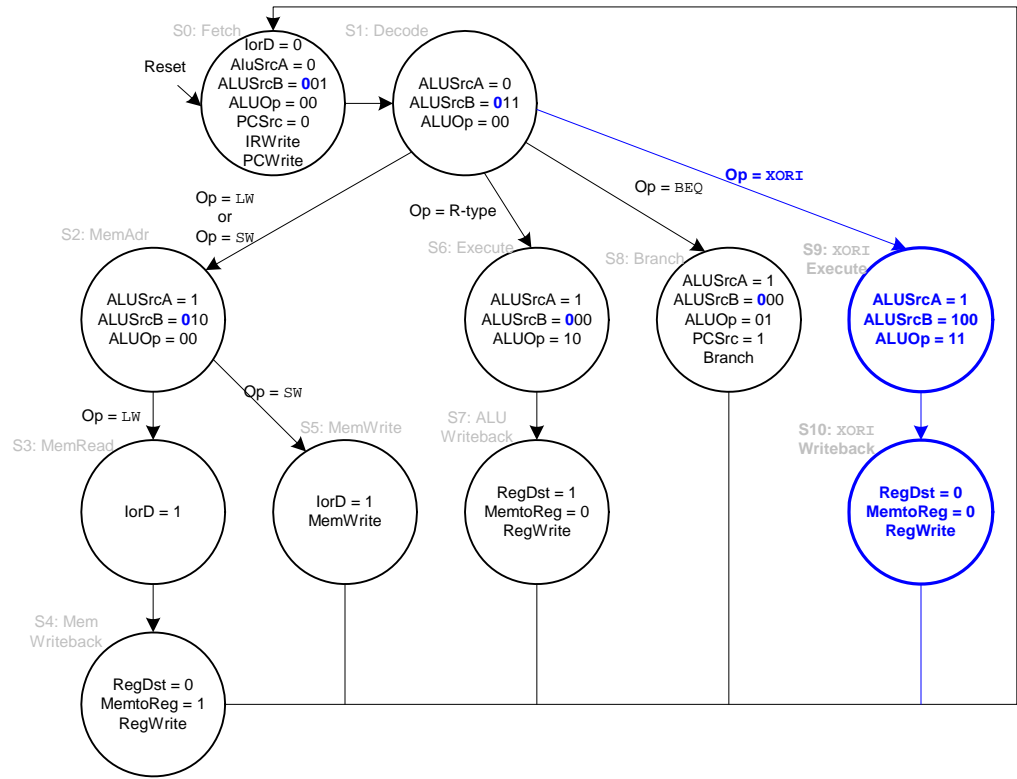

ALUControl _{3:0}	Function
0000	A AND B
0001	A OR B
0010	A + B
0011	not used
1000	A AND \overline{B}
1001	A OR \overline{B}
1010	A - B
1011	SLT
0100	A XOR B

ALUOp	Funct	ALUControl
00	X	0010 (add)
01	X	1010 (subtract)
11	X	0100 (xor)
10	100000 (add)	0010 (add)
10	100010 (sub)	1010 (subtract)
10	100100 (and)	0000 (and)
10	100101 (or)	0001 (or)
10	101010 (slt)	1011 (set less than)

TABLE 7.18 ALU decoder truth table for `xori`

Next, we modify the datapath. We change the buswidth of the *ALUControl* signal from 3 bits to 4 bits and the *ALUSrcB* signal from 2 bits to 3 bits. We also extend the SrcB mux and add a zero-extension unit.

(d) jr
First, we extend the ALU Decoder for jr.

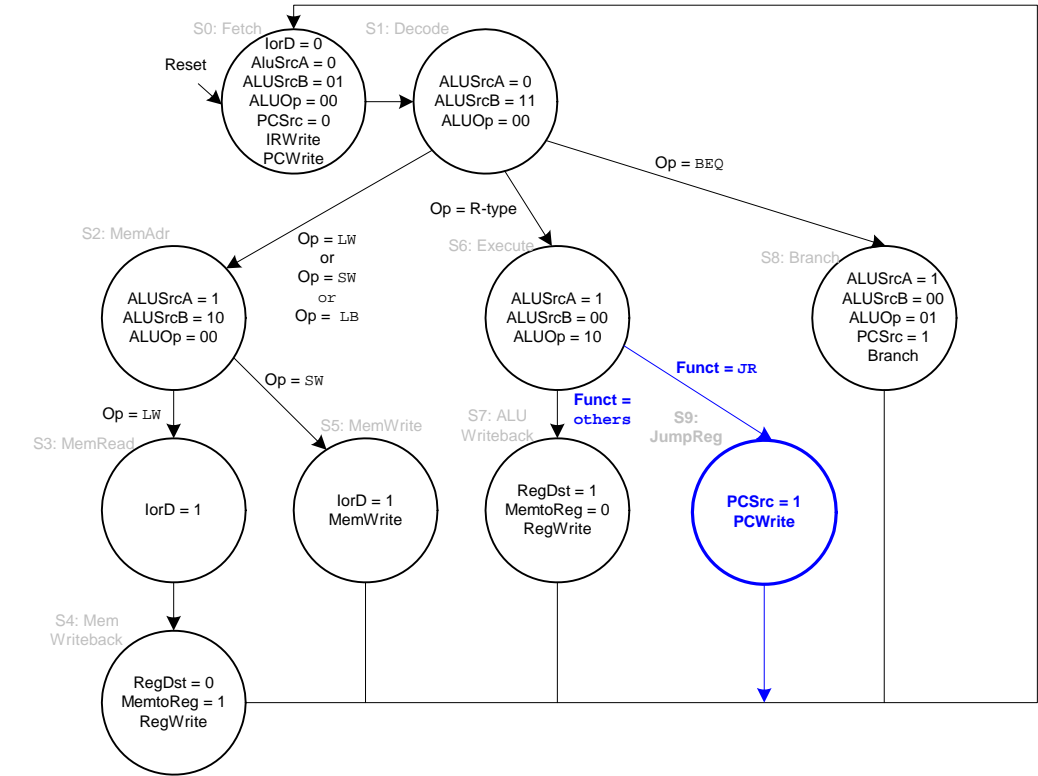

ALUOp	Funct	ALUControl
00	X	010 (add)
X1	X	110 (subtract)
1X	100000 (add)	010 (add)
1X	100010 (sub)	110 (subtract)
1X	100100 (and)	000 (and)
1X	100101 (or)	001 (or)

TABLE 7.19 ALU decoder truth table with jr

ALUOp	Funct	ALUControl
1X	101010 (slt)	111 (set less than)
1X	001000 (jr)	010 (add)

TABLE 7.19 ALU decoder truth table with jr

Next, we modify the main controller. The datapath requires no modification.

Exercise 7.14

(a) bne

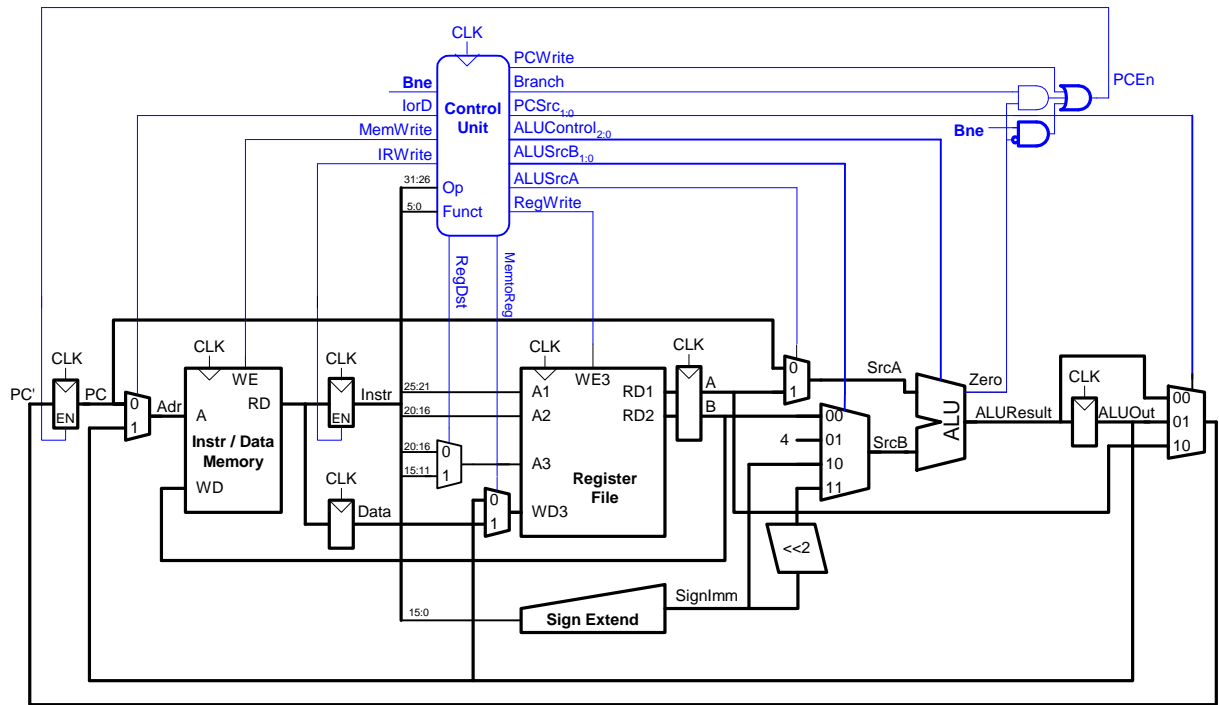

FIGURE 7.15 Modified datapath for `bne`

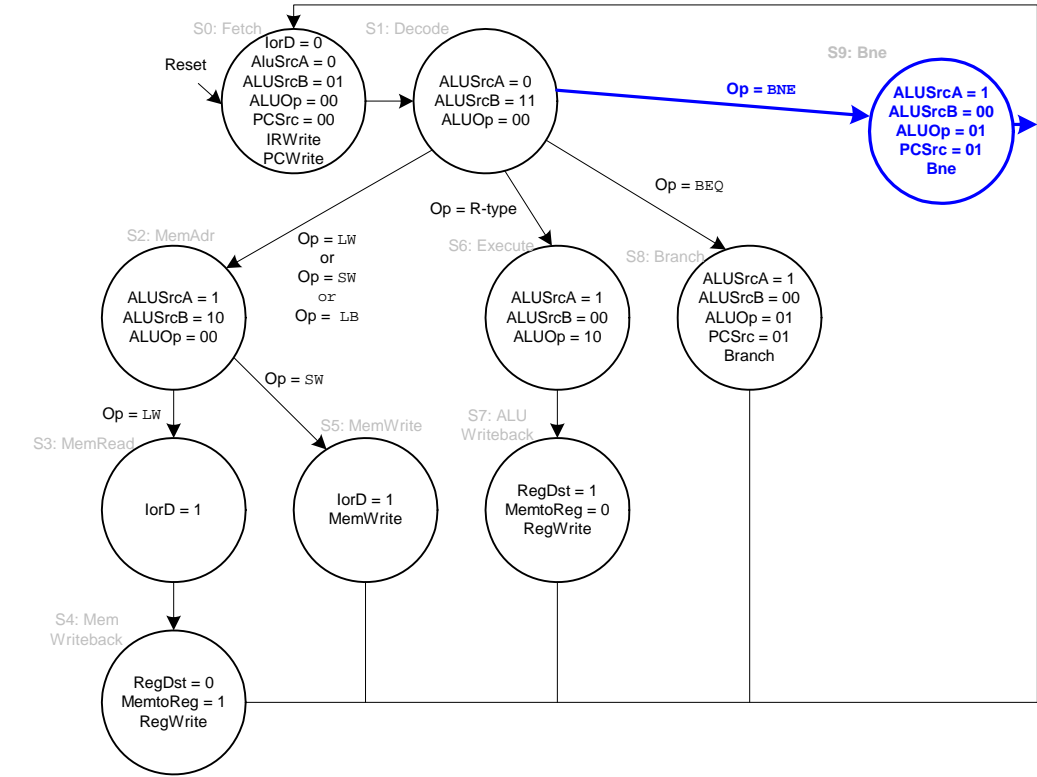

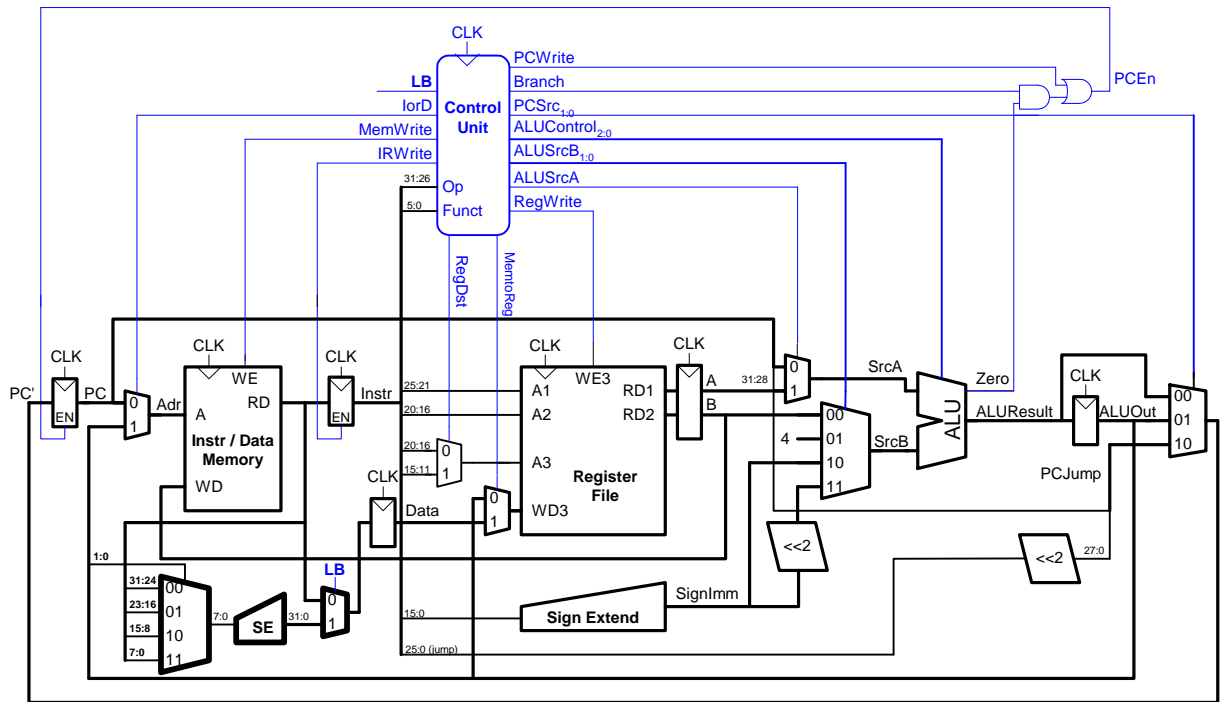

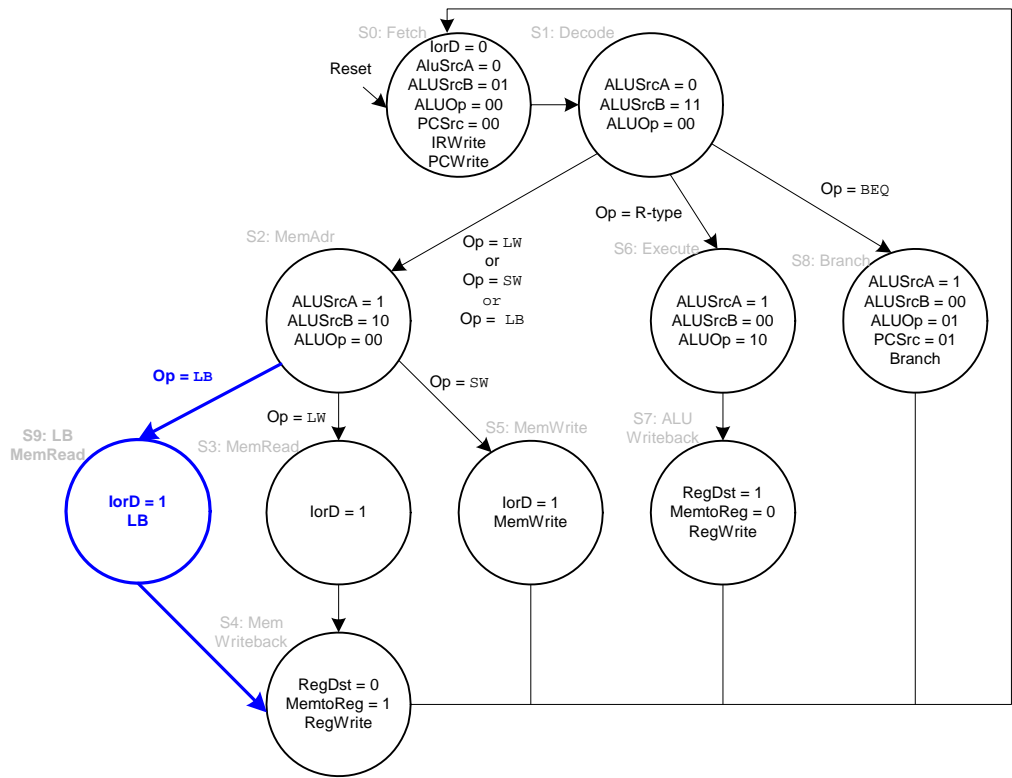

FIGURE 7.16 Modified FSM for `bne`

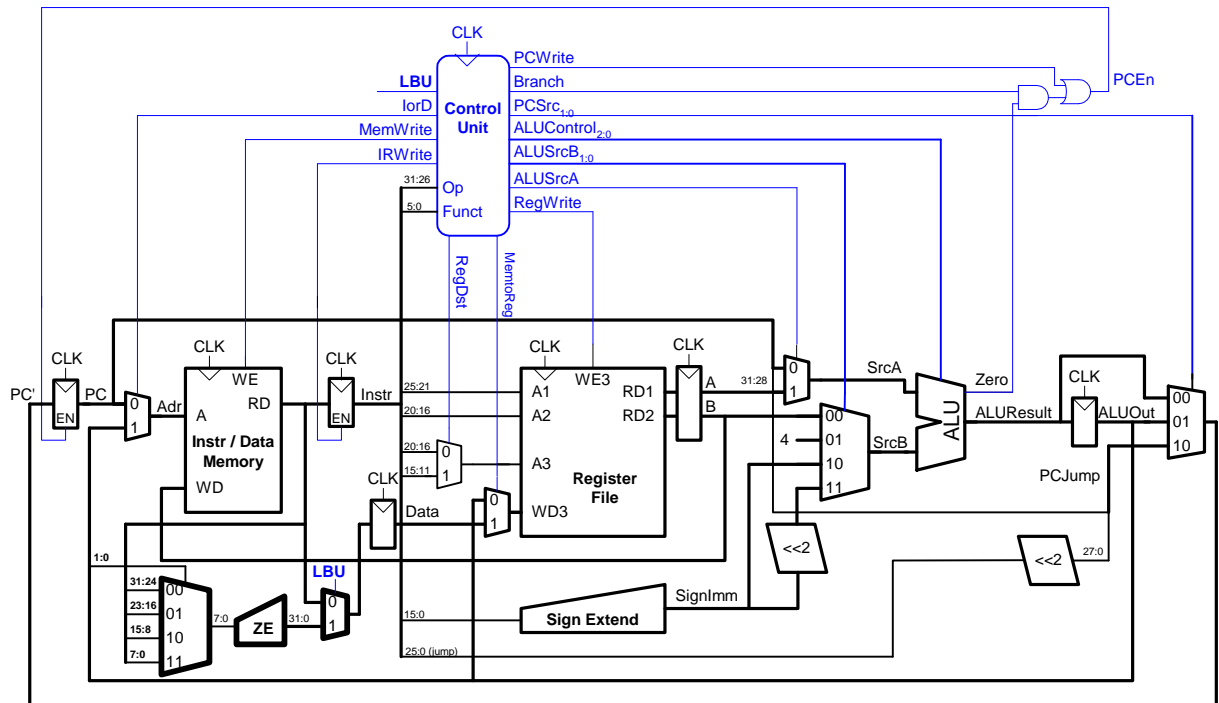

7.14 (b) 1b

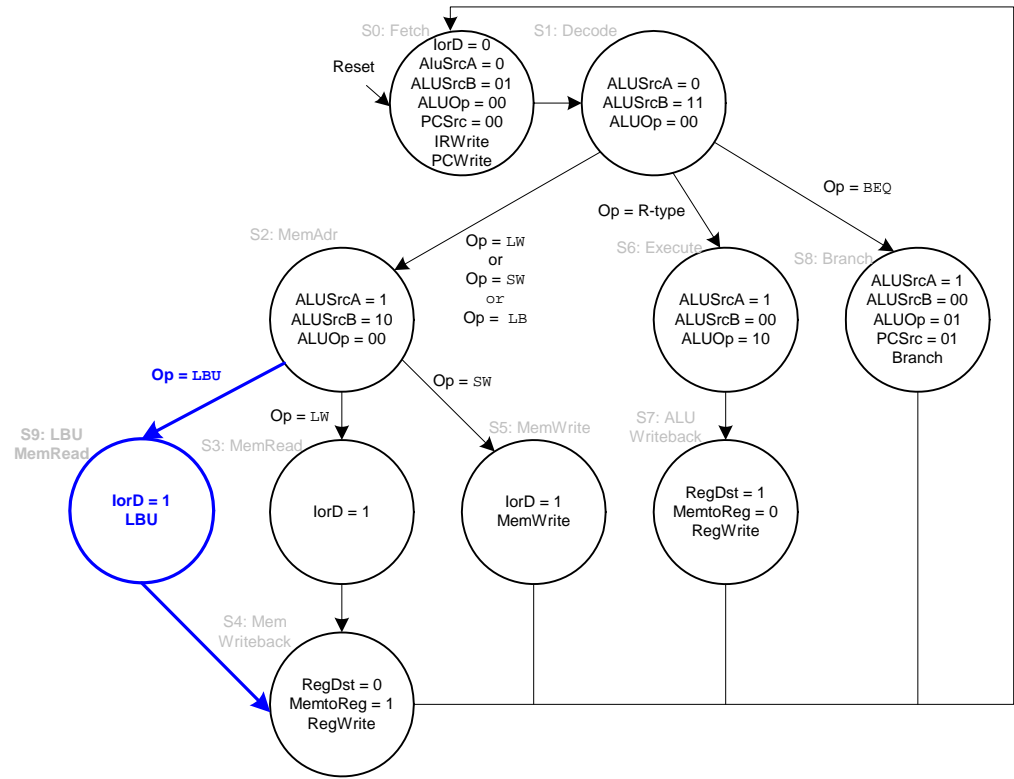

* The SE unit is a sign extension unit.

7.14 (c) lbu

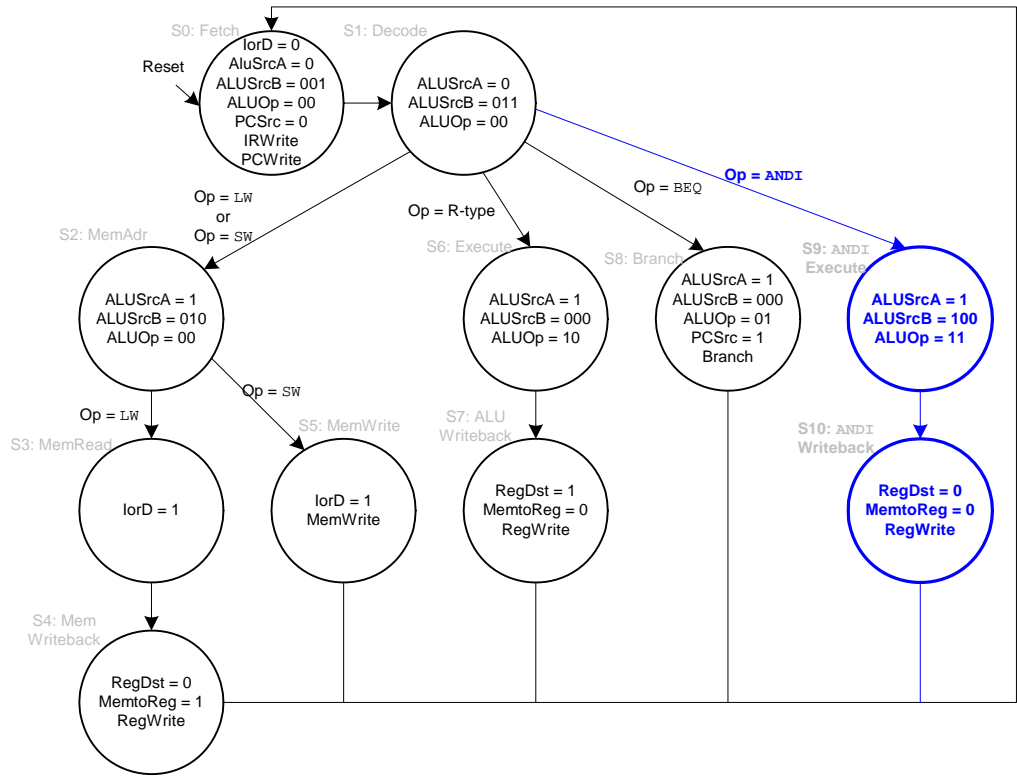

* The ZE unit is a zero extension unit.

7.14 (d) and i

ALUOp	Funct	ALUControl
00	X	010 (add)
01	X	110 (subtract)
11	X	000 (and)
10	100000 (add)	010 (add)
10	100010 (sub)	110 (subtract)
10	100100 (and)	000 (and)
10	100101 (or)	001 (or)
10	101010 (slt)	111 (set less than)

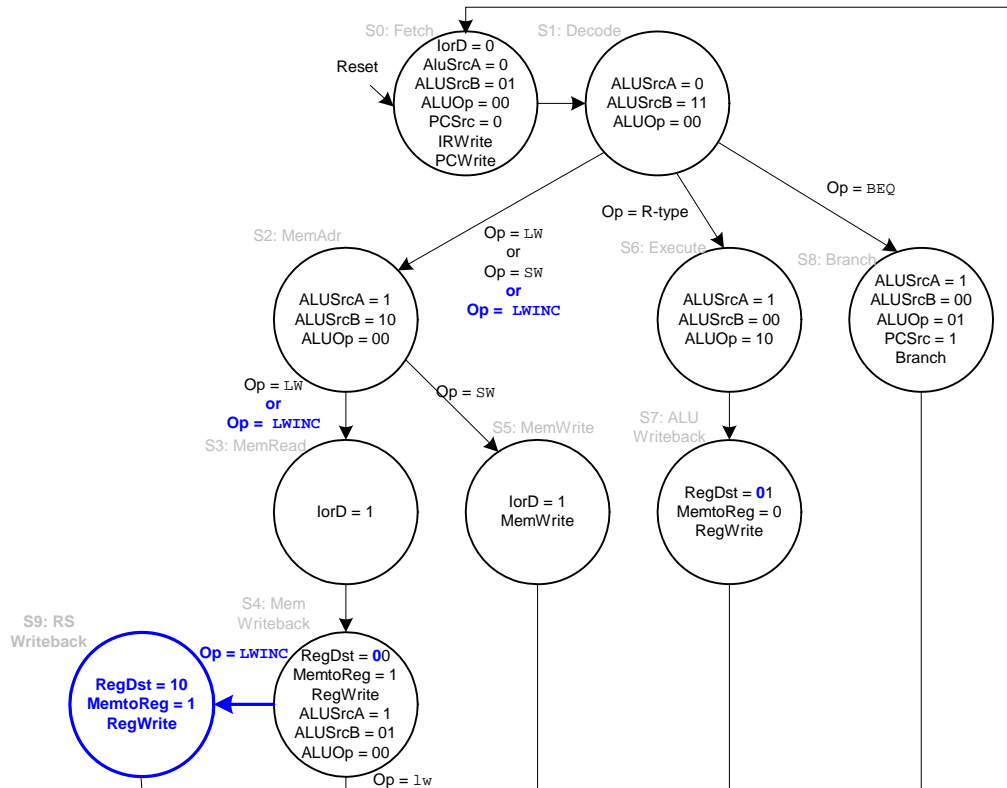

TABLE 7.20 ALU decoder truth table

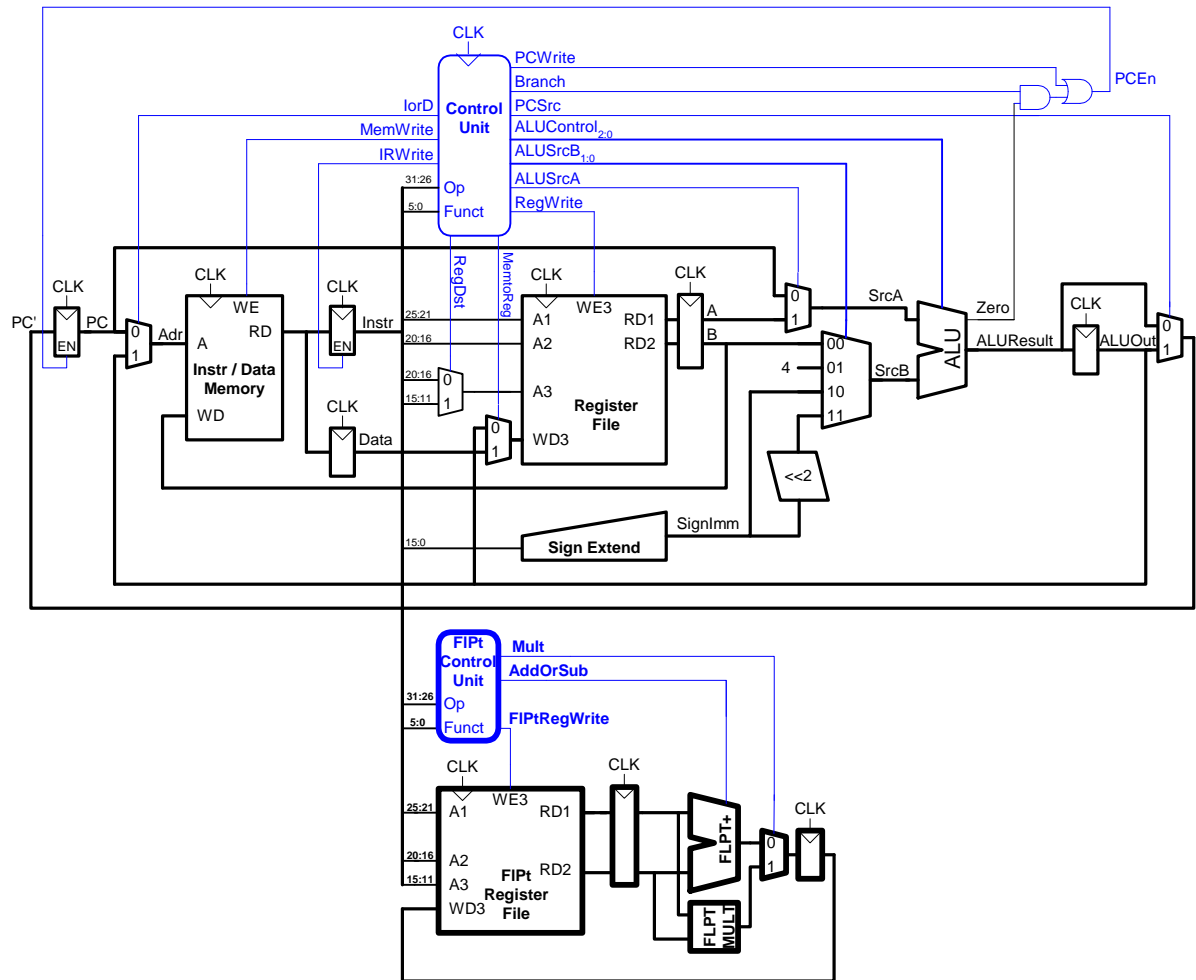

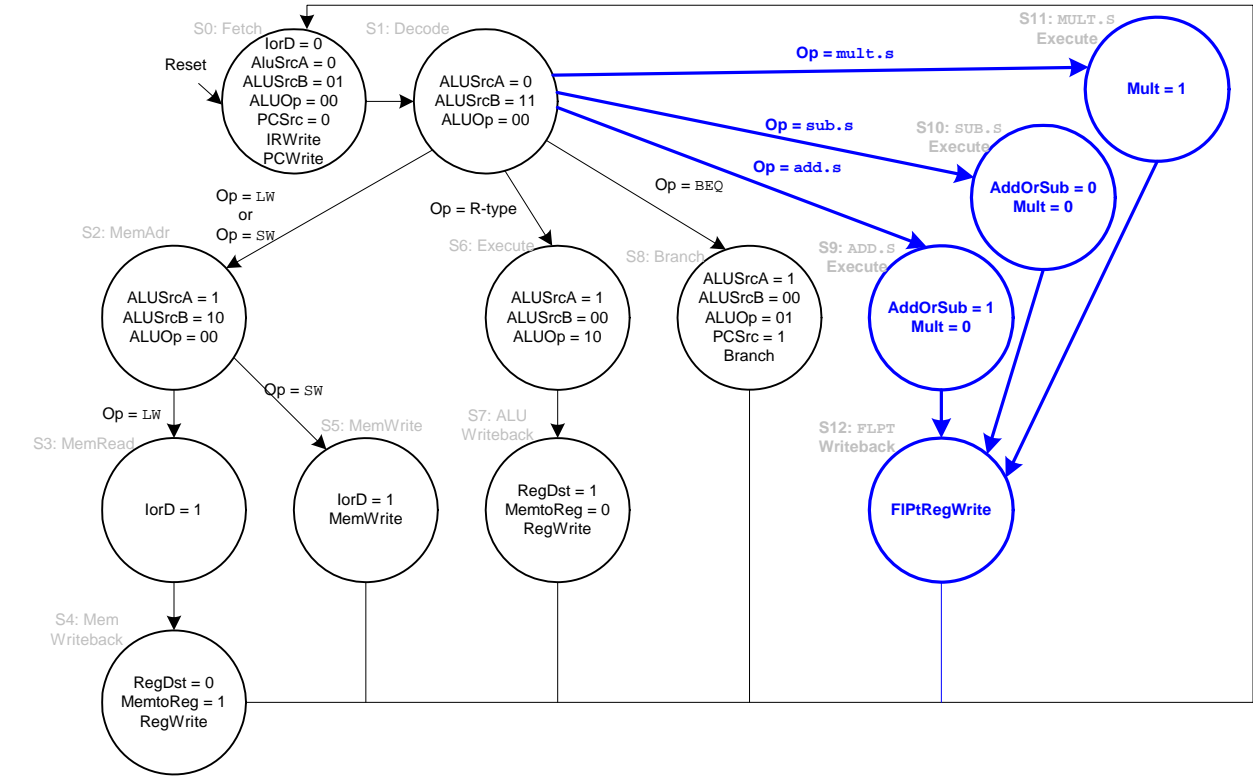

Exercise 7.15

Yes, it is possible to add this instruction without modifying the register file. First we show the modifications to the datapath. The only modification is adding the `rs` field of the instruction (`Instruction25:21`) to the input of the write address mux of the register file. `RegDst` must be expanded to two bits.

The finite state machine requires another state to write the `rs` register. If execution time is critical, another adder could be placed just after the A/B register to add 4 to A. Then in State 3, as memory is read, the register file could be written back with the incremented `rs`. In that case, `lwinc` would require the same number of cycles as `lw`. The penalty, however, would be chip area, and thus power and cost.

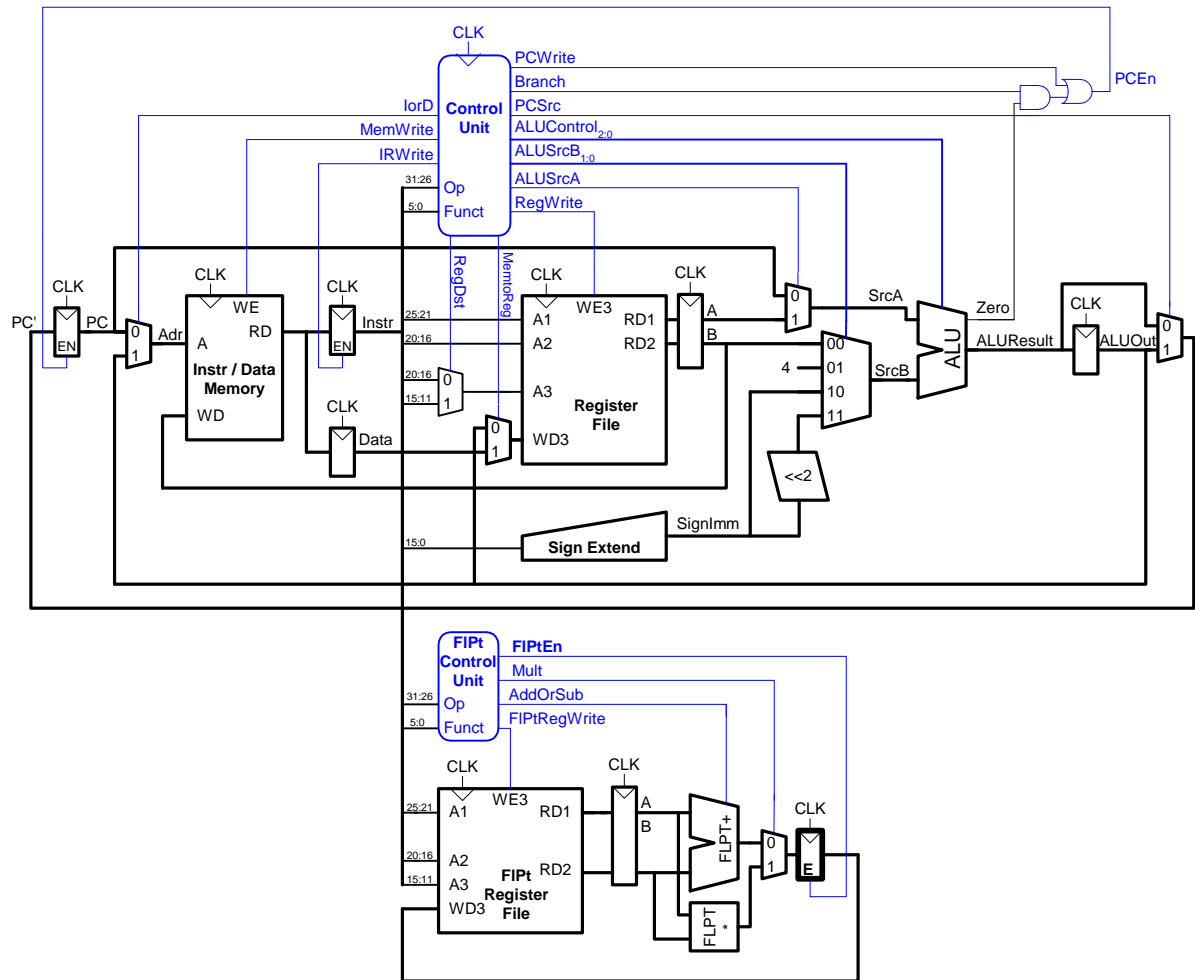

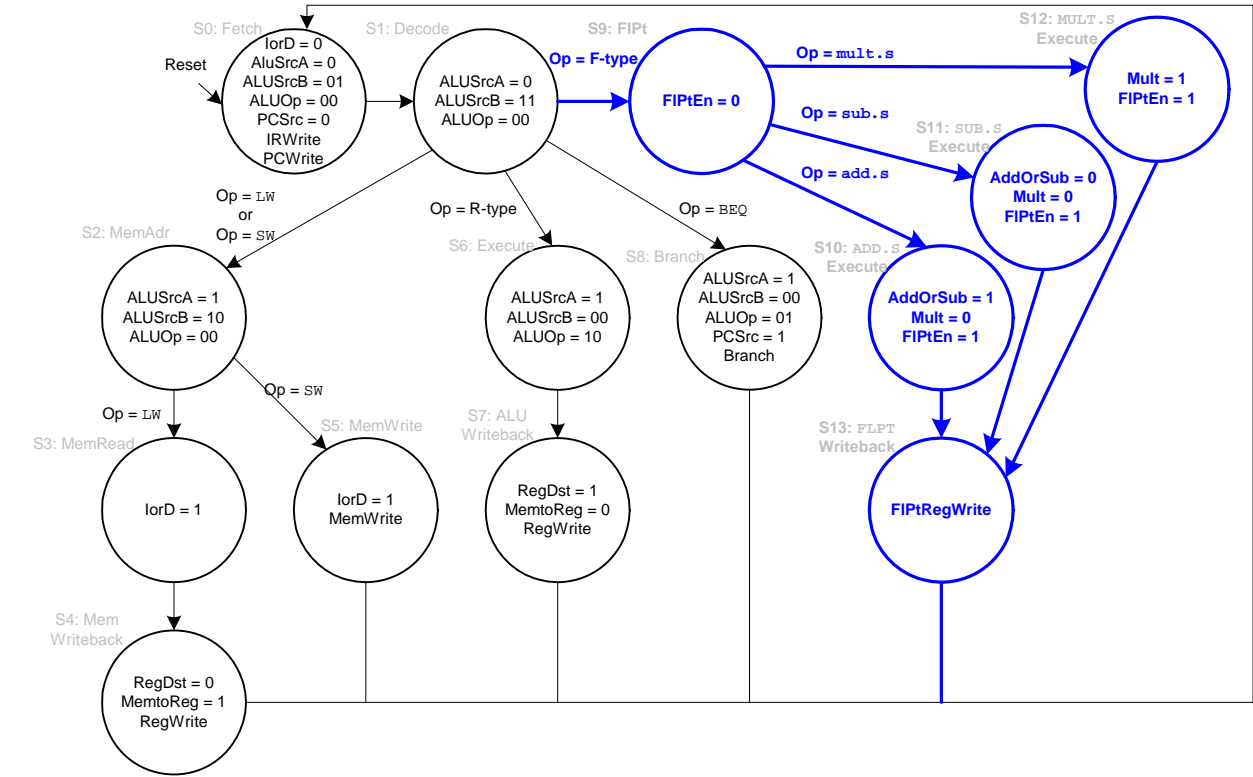

Exercise 7.17

We add an enable signal, *FIPtEn*, to the result register.

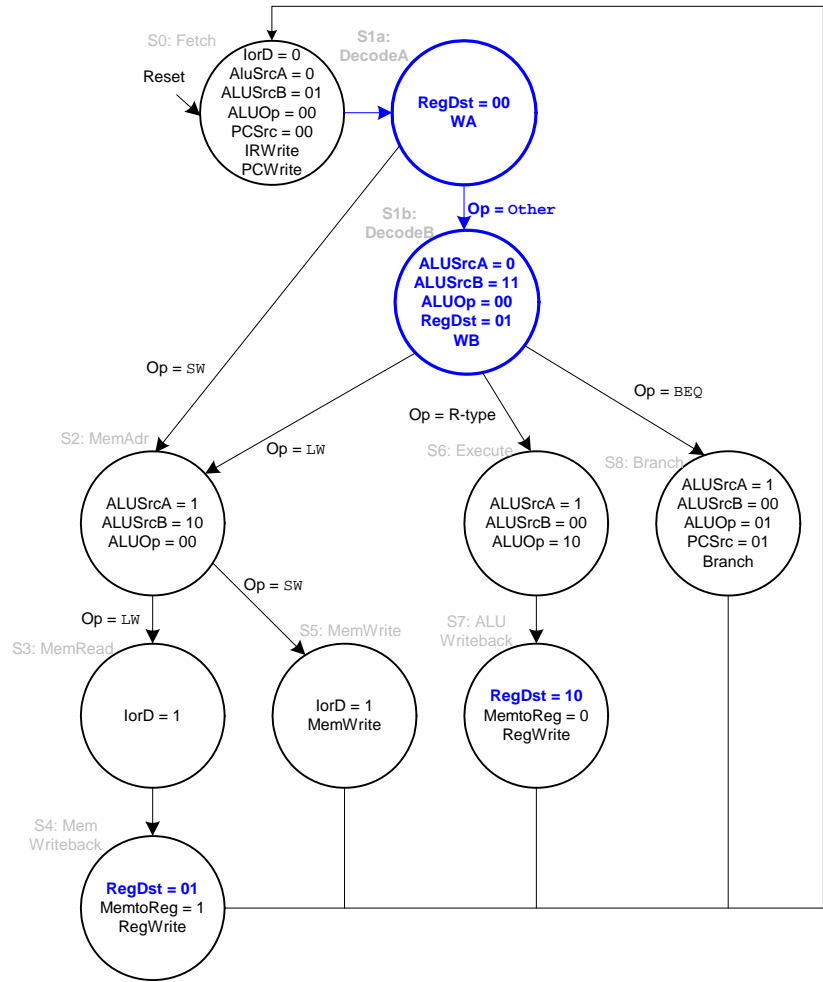

Exercise 7.18

Your friend should work on the memory unit. It should have a delay of 225ps to equal the delay of the ALU plus multiplexer. The cycle time is now 300 ps.

Exercise 7.19

Because the ALU is not on the critical path, the speedup in performance of the ALU does not affect the cycle time. Thus, the cycle time, given in Example 7.8, is still 325 ps. Given the instruction mix in Example 7.7, the overall execution time for 100 billion instructions is still 133.9 seconds.

Exercise 7.20

Exercise 7.22

$$\text{Average CPI} = (0.25)(6) + (0.52)(5) + (0.1 + 0.11)(4) + (0.02)(3) = 5$$

Exercise 7.23

$$4 + (3 + 4 + 3) \times 5 + 3 = \mathbf{57 \text{ clock cycles}}$$

The number of instructions executed is $1 + (3 \times 5) + 1 = 17$. Thus, the CPI
= 57 clock cycles / 17 instructions = **3.35 CPI**

Exercise 7.24

$(4 \times 3) + (4 + 3 + 4 + 4 + 3) \times 10 + (4 + 3) = 199$ clock cycles

The number of instructions executed is $3 + (5 \times 10) + 2 = 55$. Thus, the CPI
= 199 clock cycles / 55 instructions = **3.62 CPI**.

Exercise 7.25

MIPS Multicycle Processor

SystemVerilog

Exercise 7.28

\$s1 is written, \$t0 is read in cycle 5.

Exercise 7.29

\$s0 is written, \$t4 and \$t5 are read in cycle 5.

Exercise 7.30

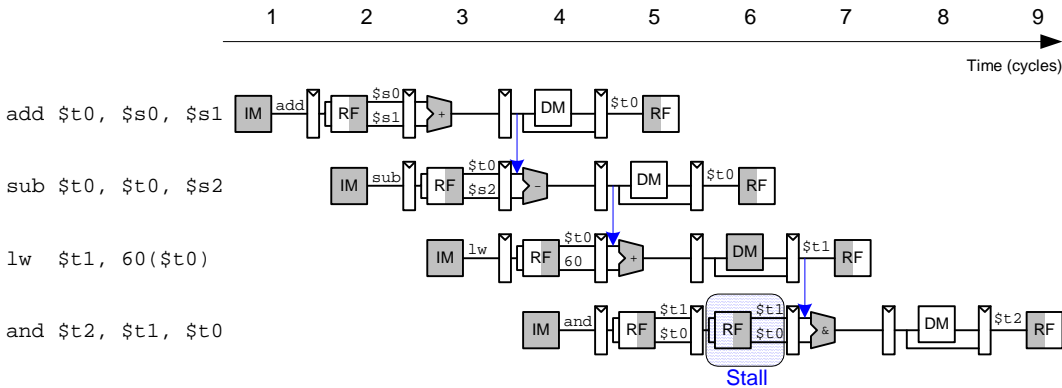

FIGURE 7.19 Abstract pipeline for Exercise 7.30

Exercise 7.31

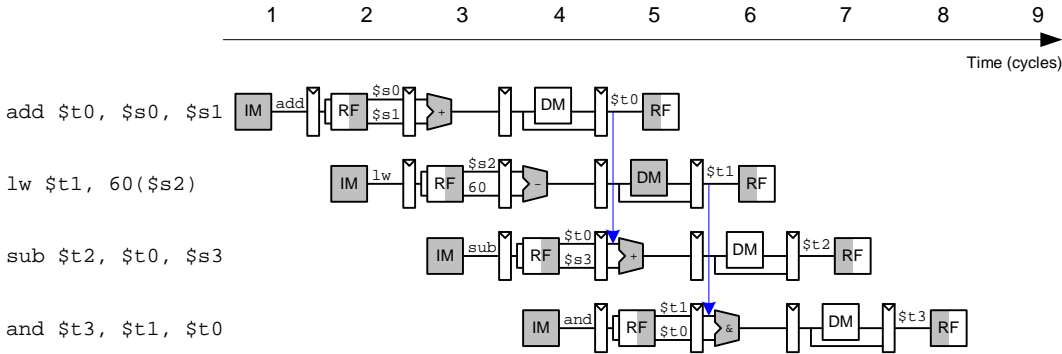

FIGURE 7.20 Abstract pipeline for Exercise 7.31

Exercise 7.32

It takes $1 + 4(5) + 2 = \mathbf{23}$ clock cycles to issue all the instructions.

instructions = $1 + 3(5) + 1 = 17$

CPI = 23 clock cycles / 17 instructions = **1.35**.

Exercise 7.33

It takes $3 + 6(10) + 3 = \mathbf{66 \text{ clock cycles}}$ to issue all the instructions.

$\# \text{ instructions} = 3 + 5(10) + 2 = 55$

$\text{CPI} = 66 \text{ clock cycles} / 55 \text{ instructions} = \mathbf{1.2}.$

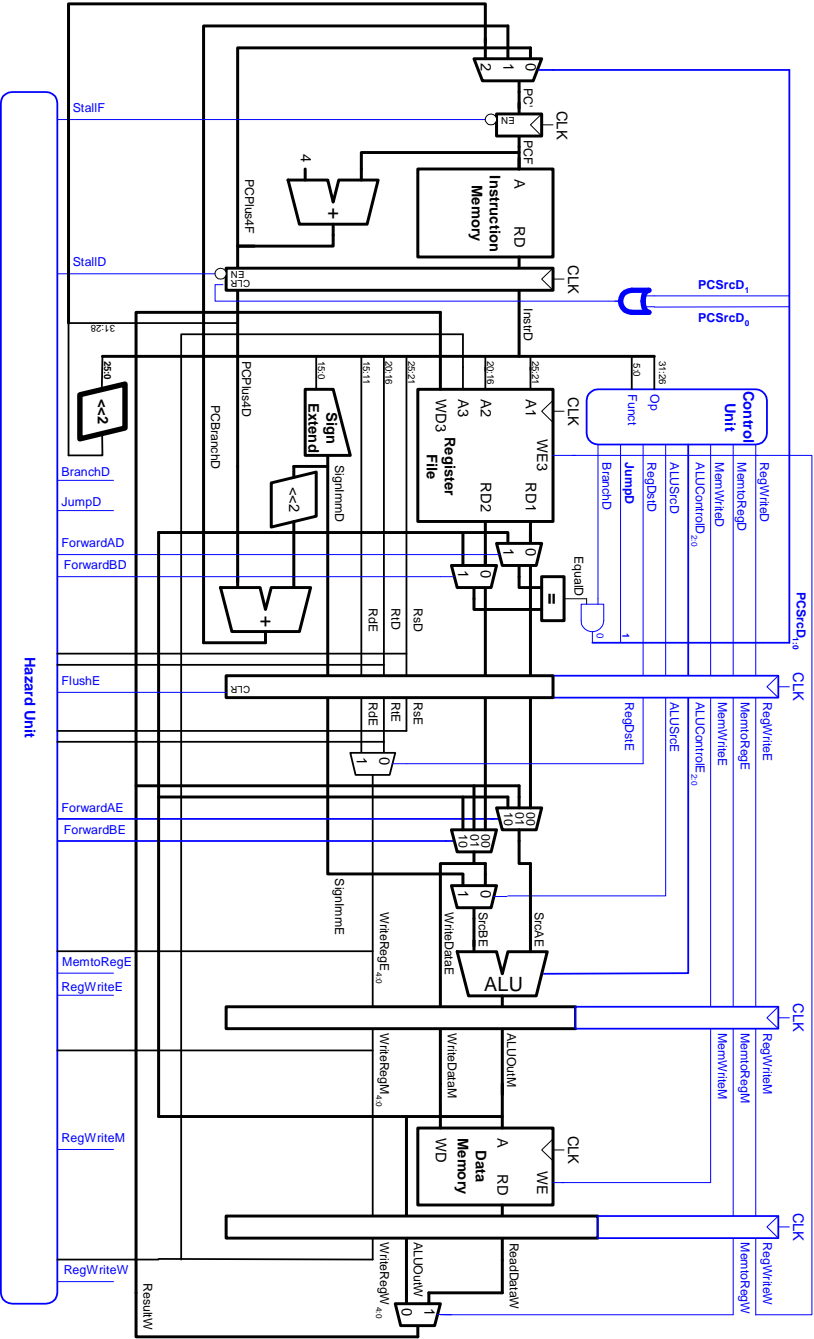

Exercise 7.34

`addi` requires no additional changes to the datapath, only changes to the control. The main decoder is modified to accommodate `addi` the same as it was for the single-cycle processor (Table 7.4) repeated in Table 7.21 for convenience.

Instruction	opcode	RegWrite	RegDst	ALUSrc	Branch	MemWrite	MemtoReg	ALUOp
R-type	000000	1	1	0	0	0	0	10
lw	100011	1	0	1	0	0	1	00
sw	101011	0	X	1	0	1	X	00
beq	000100	0	X	0	1	0	X	01
addi	001000	1	0	1	0	0	0	00

TABLE 7.21 Main decoder truth table enhanced to support `addi`

Exercise 7.35

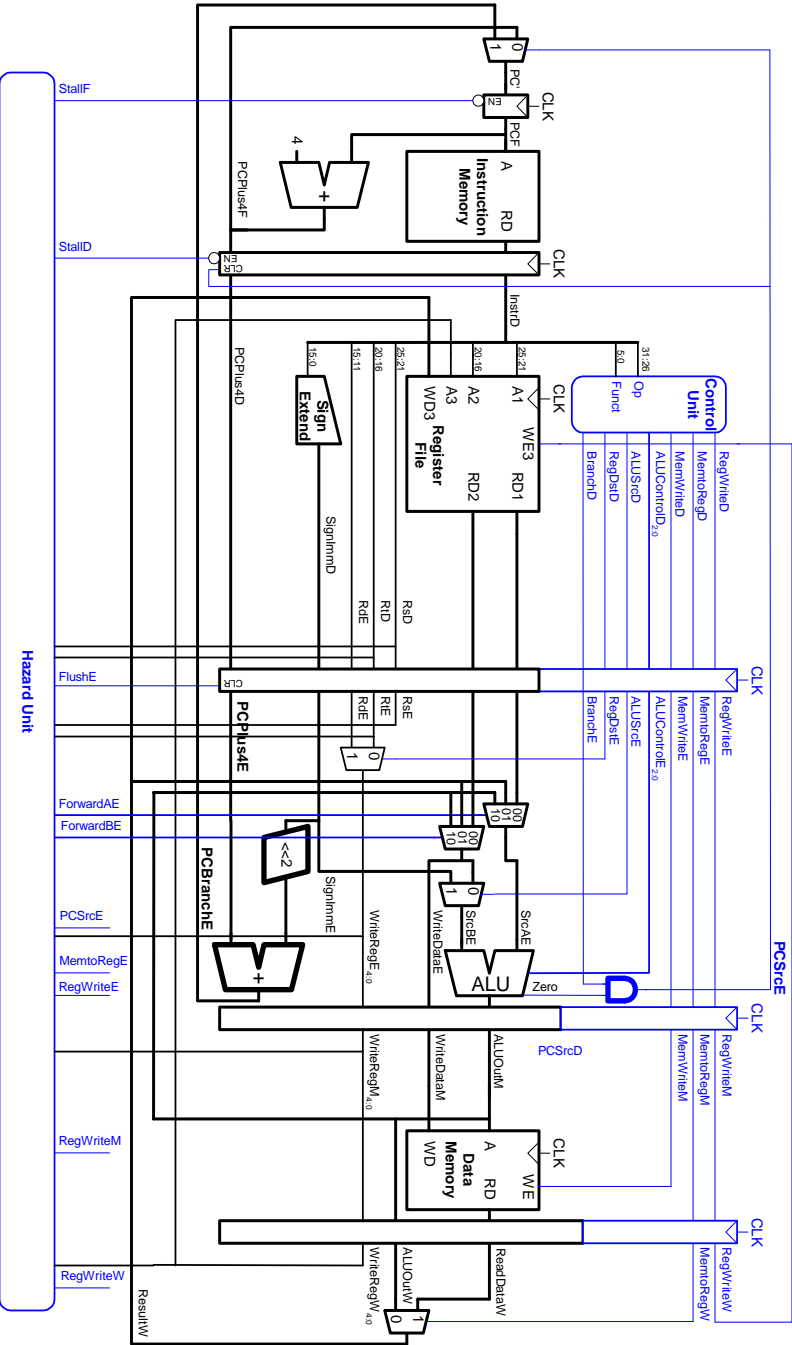

Instruction	opcode	RegWrite	RegDst	ALUSrc	Branch	MemWrite	MemtoReg	ALUOp	JumpD
R-type	000000	1	1	0	0	0	0	10	0
lw	100011	1	0	1	0	0	1	00	0
sw	101011	0	X	1	0	1	X	00	0
beq	000100	0	X	0	1	0	X	01	0
j	000010	0	X	X	0	0	X	XX	1

TABLE 7.22 Main decoder truth table enhanced to support j

We must also write new equations for the flush signal, *FlushE*.

$$\text{FlushE} = \text{lwstall} \text{ OR } \text{branchstall} \text{ OR } \text{JumpD}$$

Exercise 7.36

The Hazard Unit must no longer produce the ForwardAD and ForwardBD signals. PCPlus4 must also be passed through the pipeline register to the Execute stage. Also, the FlushE signal requires new hardware, as described by the following Boolean expression:

$$\text{FlushE} = \text{lwstall} \text{ OR } \text{PCSrcE}$$

CPI calculation:

Loads take 1 clock cycle when there is no dependency and 2 when the processor must stall for a dependency, so they have a CPI of $(0.6)(1) + (0.4)(2) = 1.4$. Branches take 1 clock cycle when they are predicted properly and 3 when they are not, so they have a CPI of $(0.75)(1) + (0.25)(3) = 1.5$. Jumps always have a CPI of 2. All other instructions have a CPI of 1. Hence, for this benchmark, Average CPI = $(0.25)(1.4) + (0.1)(1) + (0.11)(1.5) + (0.02)(2) + (0.52)(1) = 1.175$.

Cycle time calculation:

We modify Equation 7.5 to correspond to our new hardware. Only the Decode and Execute stages change.

$$T_c = \max \left(\begin{array}{l} t_{\text{pcq}} + t_{\text{memread}} + t_{\text{setup}} \\ 2(t_{\text{RFread}} + t_{\text{setup}}) \\ t_{\text{pcq}} + t_{\text{mux}} + t_{\text{mux}} + t_{\text{ALU}} + t_{\text{AND}} + t_{\text{mux}} + t_{\text{setup}} \\ t_{\text{pcq}} + t_{\text{memwrite}} + t_{\text{setup}} \\ 2(t_{\text{pcq}} + t_{\text{mux}} + t_{\text{RFwrite}}) \end{array} \right) \left\{ \begin{array}{l} \text{Fetch} \\ \text{Decode} \\ \text{Execute} \\ \text{Memory} \\ \text{Writeback} \end{array} \right.$$

Thus, the cycle time of the pipelined processor is $T_{c,3} = \max(30 + 250 + 20, 2(150 + 20), 30 + 25 + 25 + 200 + 15 + 25 + 20, 30 + 220 + 20, 2(30 + 25 + 100)) = \max(300, 340, 340, 270, 310) = \mathbf{340 \text{ ps}}$. The Decode and Execute stages tie for the critical path.

According to Equation 7.1, the total execution time is $T_3 = (100 \times 10^9 \text{ instructions})(1.175 \text{ cycles / instruction})(340 \times 10^{-12} \text{ s/cycle}) = \mathbf{39.95 \text{ s}}$.

This compares with the execution time of 63.3 s when the branch prediction was performed in the Decode stage (see Example 7.10).

Exercise 7.37

The critical path is the Decode stage, according to Equation 7.5:

$T_{c3} = \max(30 + 250 + 20, 2(150 + 25 + 40 + 15 + 25 + 20), 30 + 25 + 25 + 200 + 20, 30 + 220 + 20, 2(30 + 25 + 100)) = \max(300, 550, 300, 270, 310) = 550$ ps. The next slowest stage is 310 ps for the writeback stage, so it doesn't make sense to make the Decode stage any faster than that.

The slowest unit in the Decode stage is the register file read (150 ps). We need to reduce the cycle time by $550 - 310 = 240$ ps. Thus, we need to reduce the register file read delay by $240/2 = 120$ ps to $(150 - 120) = \mathbf{30}$ ps.

The new cycle time is **310 ps**.

Exercise 7.38

Increasing the ALU delay by 20% (from 200 ps to 240 ps) does not change the critical path (the critical path is the Decode stage in either case, not the Execute stage). Thus, a 20% increase or decrease in delay in the ALU will not affect the cycle time.

Exercise 7.39

$$\text{CPI} = 0.25(1 + 0.5 \cdot 6) + 0.1(1) + 0.11(1 + 0.3 \cdot 1) + 0.02(2) + 0.52(1) = 1.8$$

$$\text{Execution Time} = (100 \times 10^9 \text{ instructions})(1.8 \text{ cycles/instruction})(400 \times 10^{-12} \text{ s/cycle}) = 72\text{s}$$

Exercise 7.40

MIPS Pipelined Processor

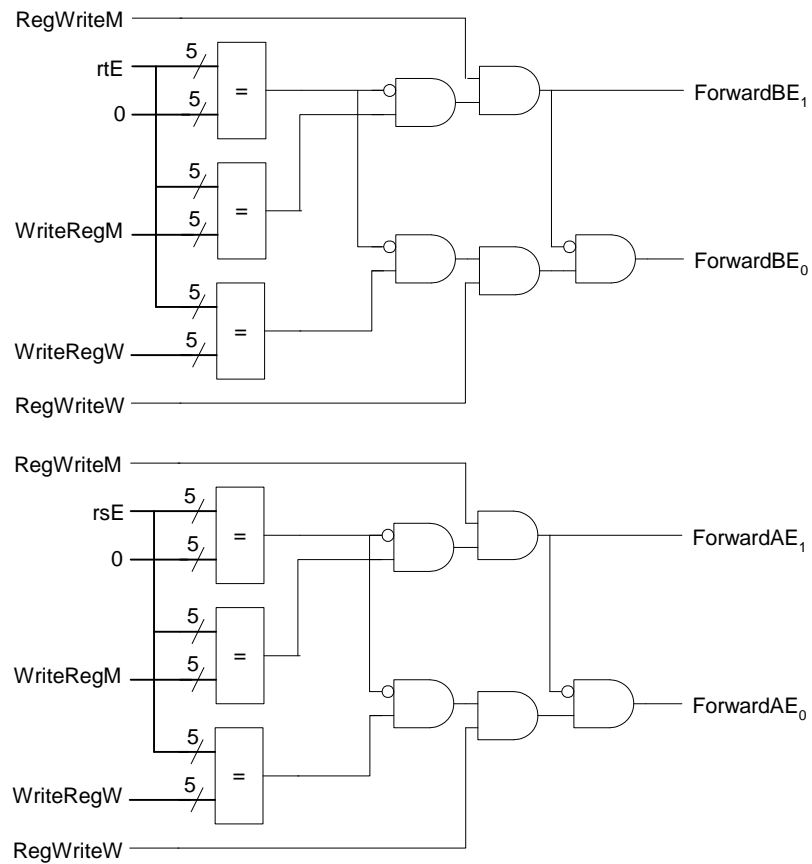

FIGURE 7.21 Hazard unit hardware for forwarding to the Execution stage

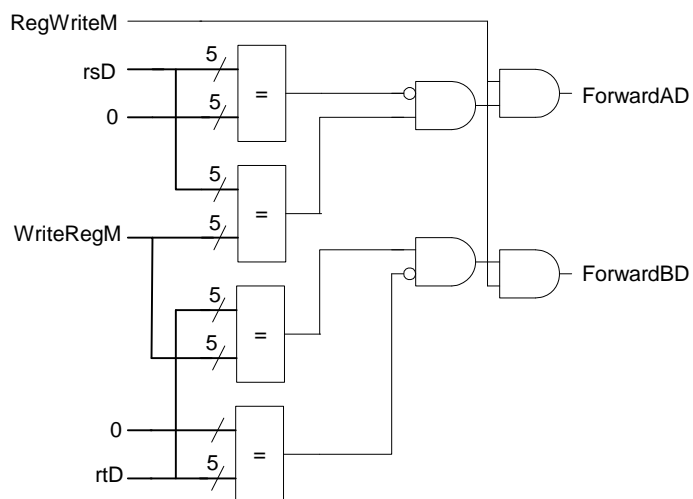

FIGURE 7.22 Hazard unit hardware for forwarding to the Decode stage

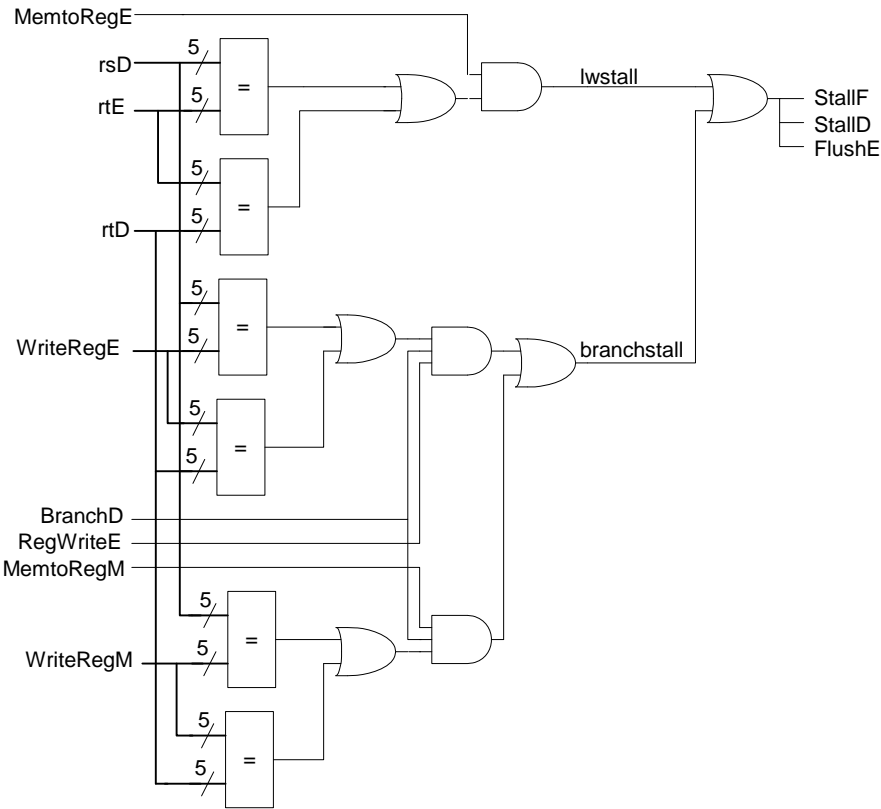

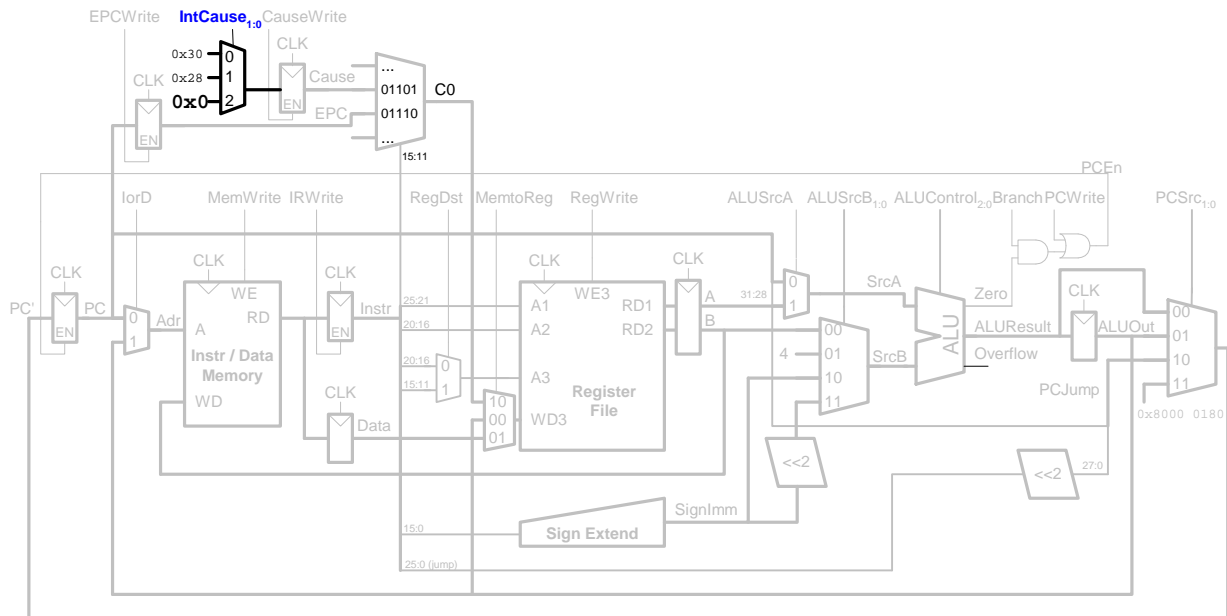

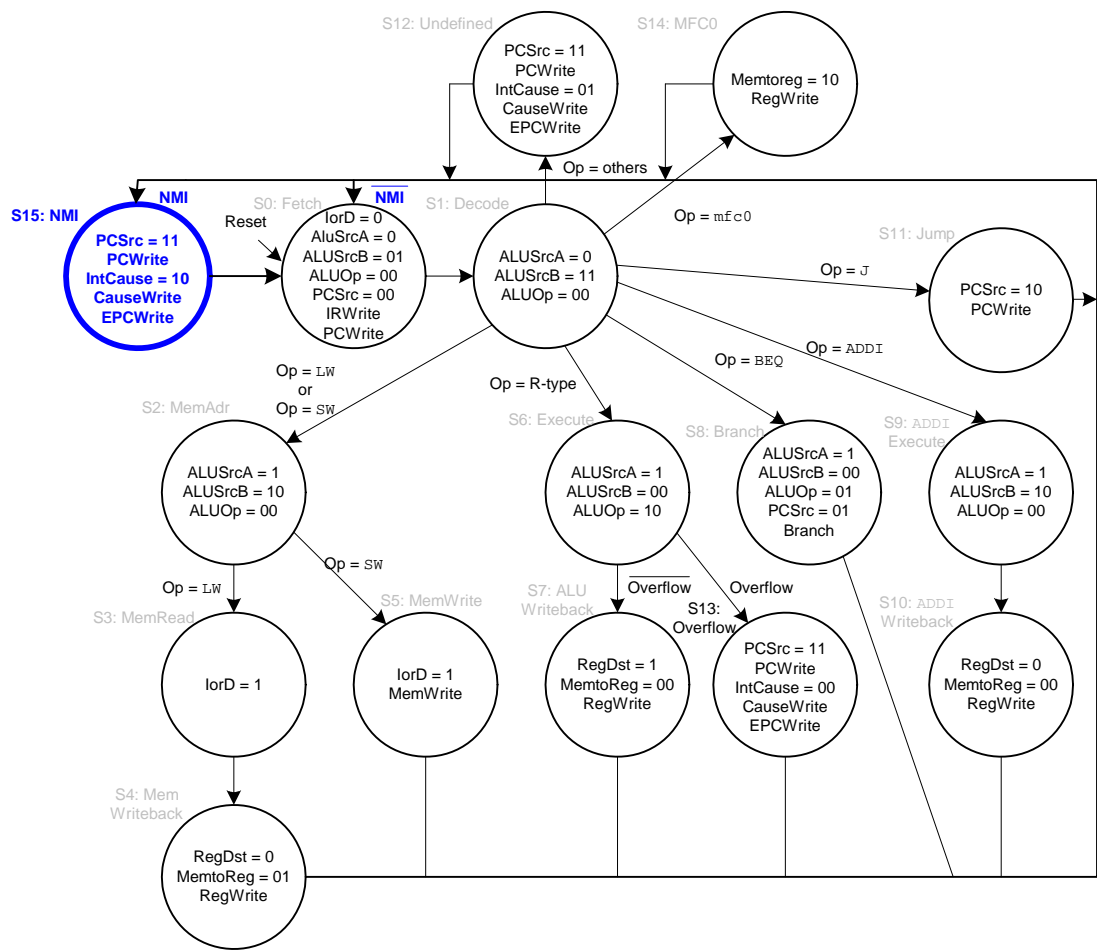

FIGURE 7.23 Hazard unit hardware for stalling/flushing in the Fetch, Decode, and Execute stages

Exercise 7.42

Question 7.1

A pipelined microprocessors with N stages offers an ideal speedup of N over nonpipelined microprocessor. This speedup comes at the cost of little extra hardware: pipeline registers and possibly a hazard unit.

Question 7.2

While pipelining offers speedup, it still has its costs. The speedup of an N stage processor is not N because of (1) sequencing overhead ($t_{pcq} + t_{setup}$, the

delay of inserting a register), (2) unequal delays of pipeline stages, (3) time to fill up the pipeline (at the beginning of a program), (4) time to drain the pipeline (at the end of a program), and (5) dependencies stalling or flushing the pipeline.

Question 7.3

A hazard in a pipelined microprocessor occurs when the execution of an instruction depends on the result of a previously issued instruction that has not completed executing. Some options for dealing with hazards are: (1) to have the compiler insert nops to prevent dependencies, (2) to have the compiler reorder the code to eliminate dependencies (inserting nops when this is impossible), (3) to have the hardware stall (or flush the pipeline) when there is a dependency, (4) to have the hardware forward results to earlier stages in the pipeline or stall when that is impossible.

Options (1 and 2): Advantages of the first two methods are that no added hardware is required, so area and, thus, cost and power is minimized. However, performance is not maximized in cases where nops are inserted.

Option 3: The advantage of having the hardware flush or stall the pipeline as needed is that the compiler can be simpler and, thus, likely faster to run and develop. Also, because there is no forwarding hardware, the added hardware is minimal. However, again, performance is not maximized in cases where forwarding could have been used instead of stalling.

Option 4: This option offers the greatest performance advantage but also costs the most hardware for forwarding, stalling, and flushing the pipeline as necessary because of dependencies.

A combination of options 2 and 4 offers the greatest performance advantage at the cost of more hardware and a more sophisticated compiler.

Question 7.4

A superscalar processor duplicates the datapath hardware to execute multiple instructions (in the same stage of a pipelined processor) at once. Ideally, the fetch stage can fetch multiple instructions per clock cycle. However, due to dependencies, this may be impossible. Thus, the costs of implementing a superscalar processor are (1) more hardware (additional register file and memory ports, additional functional units, more hazard detection and forwarding hardware, etc.) and (2) more complex fetch and commit (execution completion) algorithms. Also, because of dependencies, superscalar processors are often underutilized. Thus, for programs with a large amount of dependencies, superscalar processors can consume more area, power and cost (because of the additional hardware) without providing any speedup.

CHAPTER 8

Exercise 8.1

Answers to this question will vary.

Temporal locality: (1) making phone calls (if you called someone recently, you're likely to call them again soon). (2) using a textbook (if you used a textbook recently, you will likely use it again soon).

Spatial locality: (1) reading a magazine (if you looked at one page of the magazine, you're likely to look at next page soon). (2) walking to locations on campus - if a student is visiting a professor in the engineering department, she or he is likely to visit another professor in the engineering department soon.

Exercise 8.2

Spatial locality: One program that exhibits spatial locality is an mp3 player. Suppose a song is stored in a file as a long string of bits. If the computer is playing one part of the song, it will need to fetch the bits immediately adjacent to the ones currently being read (played).

Temporal locality: An application that exhibits temporal locality is a Web browser. If a user recently visited a Web site, the user is likely to peruse that Web site again soon.

Exercise 8.3

Repeat data accesses to the following addresses:

0x0 0x10 0x20 0x30 0x40

The miss rate for the fully associative cache is: 100%. Miss rate for the direct-mapped cache is $2/5 = 40\%$.

Exercise 8.4

Repeat data accesses to the following addresses:
0x0 0x40 0x80 0xC0

They all map to set 0 of the direct-mapped cache, but they fit in the fully associative cache. After many repetitions, the miss rate for the fully associative cache approaches 0%. The miss rate for the direct-mapped cache is 100%.

Exercise 8.5

(a) Increasing block size will increase the cache's ability to take advantage of spatial locality. This will reduce the miss rate for applications with spatial locality. However, it also decreases the number of locations to map an address, possibly increasing conflict misses. Also, the miss penalty (the amount of time it takes to fetch the cache block from memory) increases.

(b) Increasing the associativity increases the amount of necessary hardware but in most cases decreases the miss rate. Associativities above 8 usually show only incremental decreases in miss rate.

(c) Increasing the cache size will decrease capacity misses and could decrease conflict misses. It could also, however, increase access time.

Exercise 8.6

Usually. Associative caches usually have better miss rates than direct-mapped caches of the same capacity and block size because they have fewer conflict misses. However, pathological cases exist where thrashing can occur, causing the set associative cache to have a worse miss rate.

Exercise 8.7

(a) **False.**

Counterexample: A 2-word cache with block size of 1 and access pattern:
0 4 8

has a 50% miss rate with a direct-mapped cache, and a 100% miss rate with a 2-way set associative cache.

(b) **True.**

The 16KB cache is a superset of the 8KB cache. (Note: it's possible that they have the *same* miss rate.)

(c) **Usually true.**

Instruction memory accesses display great spatial locality, so a large block size reduces the miss rate.

Exercise 8.8

- (a) $b \times S \times N \times 4$ bytes
- (b) $[A - (\log_2(S) + \log_2(b) + 2)] \times S \times N$
- (c) $S = 1, N = C/b$
- (d) $S = C/b$

Exercise 8.9

Figure 8.1 shows where each address maps for each cache configuration.

Set 15	7C		
	78		
	74		
	70		
	20		
Set 7	9C 1C	7C 9C 1C	78-7C
	98 18	78 98 18	70-74
	94 14	74 94 14	
	90 10	70 90 10	20-24
	4C 8C C	4C 8C C	98-9C 18-1C
	48 88 8	48 88 8	90-94 10-14
	44 84 4	44 84 4	48-4C 88-8C 8-C
Set 0	40 80 0	40 80 0 20	40-44 80-84 0-4
	(a) Direct Mapped	(c) 2-way assoc	(d) direct mapped b=2

FIGURE 8.1 Address mappings for Exercise 8.9

- (a) **80% miss rate.** Addresses 70-7C and 20 use unique cache blocks and are not removed once placed into the cache. Miss rate is $20/25 = 80\%$.
- (b) **100% miss rate.** A repeated sequence of length greater than the cache size produces no hits for a fully-associative cache using LRU.
- (c) **100% miss rate.** The repeated sequence makes at least three accesses to each set during each pass. Using LRU replacement, each value must be replaced each pass through.
- (d) **40% miss rate.** Data words from consecutive locations are stored in each cache block. The larger block size is advantageous since accesses in the

given sequence are made primarily to consecutive word addresses. A block size of two cuts the number of block fetches in half since two words are obtained per block fetch. The address of the second word in the block will always hit in this type of scheme (e.g. address 44 of the 40-44 address pair). Thus, the second consecutive word accesses always hit: 44, 4C, 74, 7C, 84, 8C, 94, 9C, 4, C, 14, 1C. Tracing block accesses (see Figure 8.1) shows that three of the eight blocks (70-74, 78-7C, 20-24) also remain in memory. Thus, the hit rate is: $15/25 = 60\%$ and miss rate is 40%.

Exercise 8.10

- (a) **11/14 = 79% miss rate.**
- (b) **12/14 = 86% miss rate.**
- (c) **6/14 = 43% miss rate.**
- (d) **7/14 = 50% miss rate.**

Exercise 8.11

- (a) 128
- (b) 100%
- (c) ii

Exercise 8.12

(a - b)

- (c) Each tag is $32 - (c+2-n)$ bits = $(30 - (c-n))$ bits
- (d) # tag bits \times # blocks = $(30 - (c-n)) \times 2^{c+2 - b'}$

Exercise 8.13

(a)

(b) Each tag is 16 bits. There are $32K\text{words} / (2 \text{ words / block}) = 16K$ blocks and each block needs a tag: $16 \times 16K = 2^{18} = 256 \text{ Kbits}$ of tags.

(c) Each cache block requires: 2 status bits, 16 bits of tag, and 64 data bits, thus each set is $2 \times 82 \text{ bits} = \mathbf{164 \text{ bits}}$.

(d) The design must use enough RAM chips to handle both the total capacity and the number of bits that must be read on each cycle. For the data, the SRAM must provide a capacity of 128 KB and must read 64 bits per cycle (one 32-bit word from each way). Thus the design needs at least $128KB / (8KB/\text{RAM}) = 16 \text{ RAMs}$ to hold the data and $64 \text{ bits} / (4 \text{ pins/RAM}) = 16 \text{ RAMs}$ to supply the number of bits. These are equal, so the design needs exactly 16 RAMs for the data.

For the tags, the total capacity is 32 KB, from which 32 bits (two 16-bit tags) must be read each cycle. Therefore, only 4 RAMs are necessary to meet the capacity, but 8 RAMs are needed to supply 32 bits per cycle. Therefore, the design will need 8 RAMs, each of which is being used at half capacity.

With 8Ksets, the status bits require another $8K \times 4\text{-bit RAM}$. We use a $16K \times 4\text{-bit RAM}$, using only half of the entries.

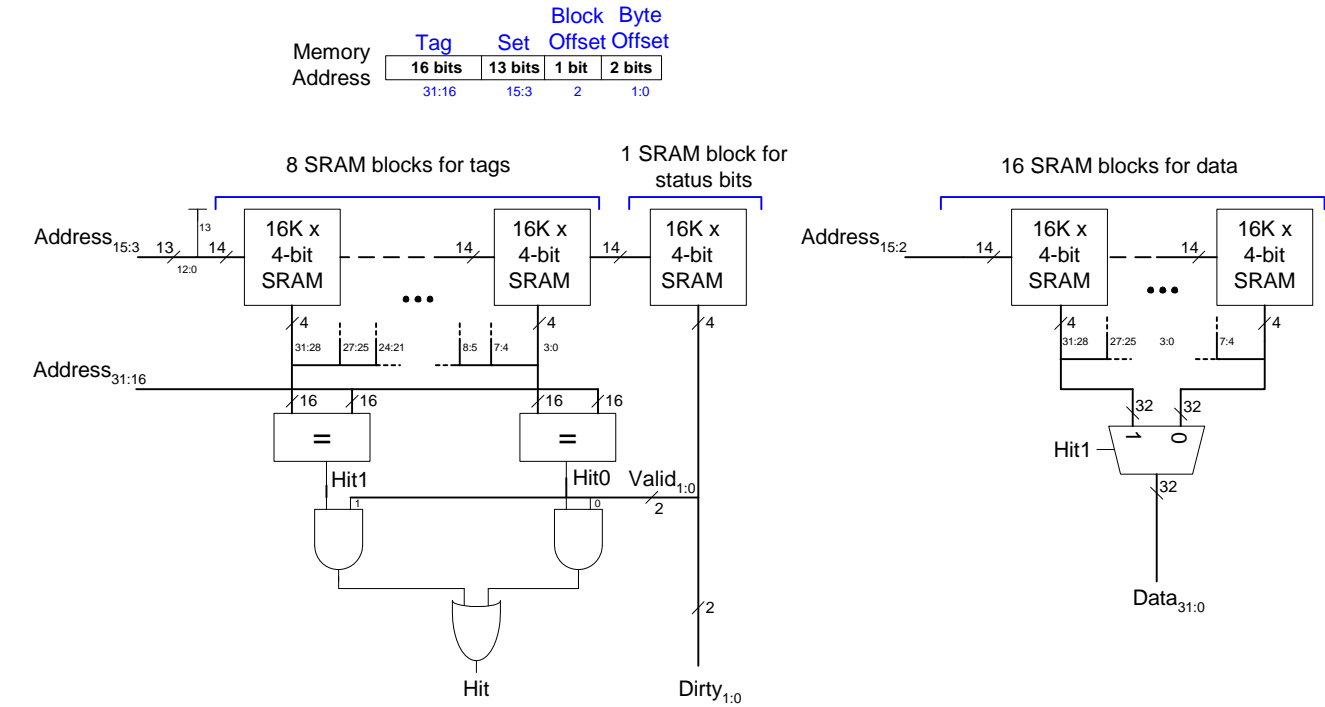

FIGURE 8.2 Cache design for Exercise 8.13

Bits 15:2 of the address select the word within a set and block. Bits 15:3 select the set. Bits 31:16 of the address are matched against the tags to find a hit in one (or none) of the two blocks with each set.

Exercise 8.14

- (a) The word in memory might be found in two locations, one in the on-chip cache, and one in the off-chip cache.
- (b) For the first-level cache, the number of sets, $S = 512 / 4 = 128$ sets. Thus, 7 bits of the address are set bits. The block size is 16 bytes / 4 bytes/word = 4 words, so there are 2 block offset bits. Thus, the number of tag bits for the first-level cache is $32 - (7+2+2) = 21$ bits.
- For the second-level cache, the number of sets is equal to the number of blocks, $S = 256$ Ksets. Thus, 18 bits of the address are set bits. The block size is 16 bytes / 4 bytes/word = 4 words, so there are 2 block offset bits. Thus, the number of tag bits for the second-level cache is $32 - (18+2+2) = 10$ bits.

(c) From Equation 8.2, $AMAT = t_{\text{cache}} + MR_{\text{cache}}(t_{\text{MM}} + MR_{\text{MM}} t_{\text{VM}})$. In this case, there is no virtual memory but there is an L2 cache. Thus,

$$AMAT = t_{\text{cache}} + MR_{\text{cache}}(t_{\text{L2cache}} + MR_{\text{L2cache}} t_{\text{MM}})$$

Where, MR is the miss rate. In terms of hit rate, $MR_{\text{cache}} = 1 - HR_{\text{cache}}$, and $MR_{\text{L2cache}} = 1 - HR_{\text{L2cache}}$. Using the values given in Table 8.6,

$$AMAT = t_a + (1 - A)(t_b + (1 - B)t_m)$$

(d)

When the first-level cache is enabled, the second-level cache receives only the “hard” accesses, ones that don’t show enough temporal and spatial locality to hit in the first-level cache. The “easy” accesses (ones with good temporal and spatial locality) hit in the first-level cache, even though they would have also hit in the second-level cache. When the first-level cache is disabled, the hit rate goes up because the second-level cache supplies both the “easy” accesses and some of the “hard” accesses.

Exercise 8.15

(a)

FIFO:

FIFO replacement approximates LRU replacement by discarding data that has been in the cache longest (and is thus least likely to be used again). A FIFO cache can be stored as a queue, so the cache need not keep track of the least recently used way in an N -way set-associative cache. It simply loads a new cache block into the next way upon a new access. FIFO replacement doesn’t work well when the *least recently used* data is not also the data fetched *longest ago*.

Random:

Random replacement requires less overhead (storage and hardware to update status bits). However, a random replacement policy might randomly evict recently used data. In practice random replacement works quite well.

(b)

FIFO replacement would work well for an application that accesses a first set of data, then the second set, then the first set again. It then accesses a third set of data and finally goes back to access the second set of data. In this case, FIFO would replace the first set with the third set, but LRU would replace the second set. The LRU replacement would require the cache to pull in the second set of data twice.

Exercise 8.16

(a)

$$AMAT = t_{\text{cache}} + MR_{\text{cache}} t_{\text{MM}}$$

With a cycle time of 1/1 GHz = 1 ns,

$$AMAT = 1 \text{ ns} + 0.05(60 \text{ ns}) = 4 \text{ ns}$$

(b) CPI = 4 + 4 = **8 cycles** (for a load)

CPI = 4 + 3 = **7 cycles** (for a store)

(c) Average CPI = (0.11 + 0.02)(3) + (0.52)(4) + (0.1)(7) + (0.25)(8) = **5.17**

(d) Average CPI = 5.17 + 0.07(60) = **9.37**

Exercise 8.17

(a)

$$AMAT = t_{\text{cache}} + MR_{\text{cache}} t_{\text{MM}}$$

With a cycle time of 1/1 GHz = 1 ns,

$$AMAT = 1 \text{ ns} + 0.15(200 \text{ ns}) = 31 \text{ ns}$$

(b) CPI = 31 + 4 = **35 cycles** (for a load)

CPI = 31 + 3 = **34 cycles** (for a store)

(c) Average CPI = (0.11 + 0.02)(3) + (0.52)(4) + (0.1)(34) + (0.25)(35) = **14.6**

(d) Average CPI = 14.6 + 0.1(200) = **34.6**

Exercise 8.18

$$2^{64} \text{ bytes} = 2^4 \text{ exabytes} = \mathbf{16 \text{ exabytes.}}$$

Exercise 8.19

$$1 \text{ million gigabytes of hard disk} \approx 2^{20} \times 2^{30} = 2^{50} \text{ bytes} = 1 \text{ petabytes}$$

$$10,000 \text{ gigabytes of hard disk} \approx 2^{14} \times 2^{30} = 2^{44} \text{ bytes} = 16 \text{ terabytes}$$

Thus, the system would need **44 bits** for the physical address and **50 bits** for the virtual address.

Exercise 8.20

- (a) **23 bits**
- (b) $2^{32}/2^{12} = 2^{20}$ **virtual pages**
- (c) $8 \text{ MB} / 4 \text{ KB} = 2^{23}/2^{12} = 2^{11}$ **physical pages**
- (d) virtual page number: **20 bits**; physical page number = **11 bits**
- (e) # virtual pages / # physical pages = 2^9 virtual pages mapped to each physical page.

Imagine a program around memory address 0x01000000 operating on data around address 0x00000000. Physical page 0 would constantly be swapped between these two virtual pages, causing severe thrashing.

- (f) 2^{20} page table entries (one for each virtual page).
- (g) Each entry uses 11 bits of physical page number and 2 bits of status information. Thus, **2 bytes** are needed for each entry (rounding 13 bits up to the nearest number of bytes).
- (h) The total table size is **2^{21} bytes**.

Exercise 8.21

- (a) **31 bits**
- (b) $2^{50}/2^{12} = 2^{38}$ **virtual pages**
- (c) $2 \text{ GB} / 4 \text{ KB} = 2^{31}/2^{12} = 2^{19}$ **physical pages**
- (d) virtual page number: **38 bits**; physical page number = **19 bits**
- (e) 2^{38} page table entries (one for each virtual page).
- (f) Each entry uses 19 bits of physical page number and 2 bits of status information. Thus, **3 bytes** are needed for each entry (rounding 21 bits up to the nearest number of bytes).
- (h) The total table size is **3×2^{38} bytes**.

Exercise 8.22

(a) From Equation 8.2, $AMAT = t_{\text{cache}} + MR_{\text{cache}} (t_{\text{MM}} + MR_{\text{MM}} t_{\text{VM}})$.
However, each data access now requires an address translation (page table or TLB lookup). Thus,

Without the TLB:

$$AMAT = t_{\text{MM}} + [t_{\text{cache}} + MR_{\text{cache}} (t_{\text{MM}} + MR_{\text{MM}} t_{\text{VM}})]$$
$$AMAT = 100 + [1 + 0.02(100 + 0.000003(1,000,000))] \text{ cycles} = \mathbf{103.06 \text{ cycles}}$$

With the TLB:

$$AMAT = [t_{\text{TLB}} + MR_{\text{TLB}}(t_{\text{MM}})] + [t_{\text{cache}} + MR_{\text{cache}} (t_{\text{MM}} + MR_{\text{MM}} t_{\text{VM}})]$$
$$AMAT = [1 + 0.0005(100)] + [1 + 0.02(100 + 0.000003 \times 1,000,000)] \text{ cycles} = \mathbf{4.11 \text{ cycles}}$$

(b) # bits per entry = valid bit + tag bits + physical page number
1 valid bit
tag bits = virtual page number = 20 bits
physical page number = 11 bits

Thus, # bits per entry = 1 + 20 + 11 = **32 bits**
Total size of the TLB = 64 × 32 bits = **2048 bits**

(c)

(d) **1 × 2048 bit SRAM**

Exercise 8.23

(a) 1 valid bit + 19 data bits (PPN) + 38 tag bits (VPN) × 128 entries = 58
* 128 bits = 7424 bits

(b)

(c) **128 × 58-bit SRAM**

Exercise 8.24

(a)

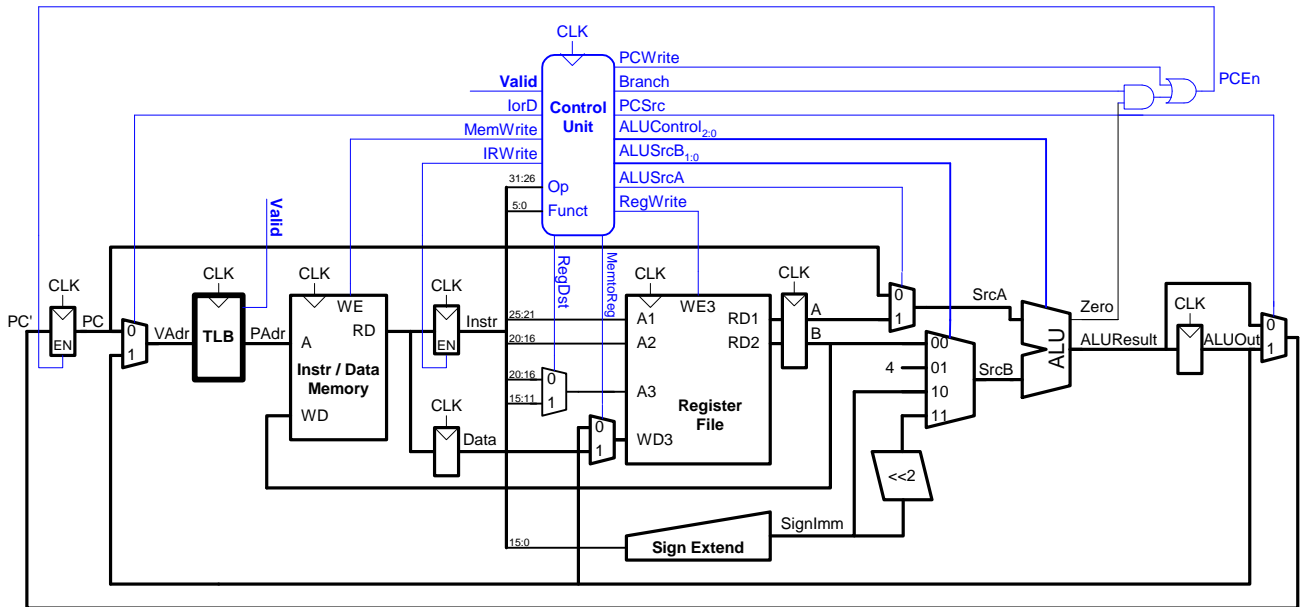

FIGURE 8.3 Multicycle MIPS processor with TLB

(b) Each instruction and data access now takes at least one additional clock cycle. On each access, the virtual address ($VAdr$ in Figure 8.3) needs to be translated to a physical address ($PAdr$). Upon a TLB miss, the page table in main memory must be accessed.

Exercise 8.25

(a) Each entry in the page table has 2 status bits (V and D), and a physical page number ($22-16 = 6$ bits). The page table has $2^{25-16} = 2^9$ entries.

Thus, the total page table size is $2^9 \times 8 \text{ bits} = \mathbf{4096 \text{ bits}}$

(b)

This would increase the virtual page number to $25 - 14 = 11$ bits, and the physical page number to $22 - 14 = 8$ bits. This would increase the page table size to:

$$2^{11} \times 10 \text{ bits} = \mathbf{20480 \text{ bits}}$$

This increases the page table by 5 times, wasted valuable hardware to store the extra page table bits.

(c)

Yes, this is possible. In order for concurrent access to take place, the number of set + block offset + byte offset bits must be less than the page offset bits.

(d) It is impossible to perform the tag comparison in the on-chip cache concurrently with the page table access because the upper (most significant) bits of the physical address are unknown until after the page table lookup (address translation) completes.

Exercise 8.26

An application that accesses large amounts of data might be written to localize data accesses to a small number of virtual pages. Particularly, data accesses can be localized to the number of pages that fit in physical memory. If the virtual memory has a TLB that has fewer entries than the number of physical pages, accesses could be localized to the number of entries in the TLB, to avoid the need of accessing the page table to perform address translation.

Exercise 8.27

(a) 2^{32} bytes = 4 gigabytes

(b) The amount of the hard disk devoted to virtual memory determines how many applications can run and how much virtual memory can be devoted to each application.

(c) The amount of physical memory affects how many physical pages can be accessed at once. With a small main memory, if many applications run at once or a single application accesses addresses from many different pages, thrashing can occur. This can make the applications dreadfully slow.

Exercise 8.28

(a)

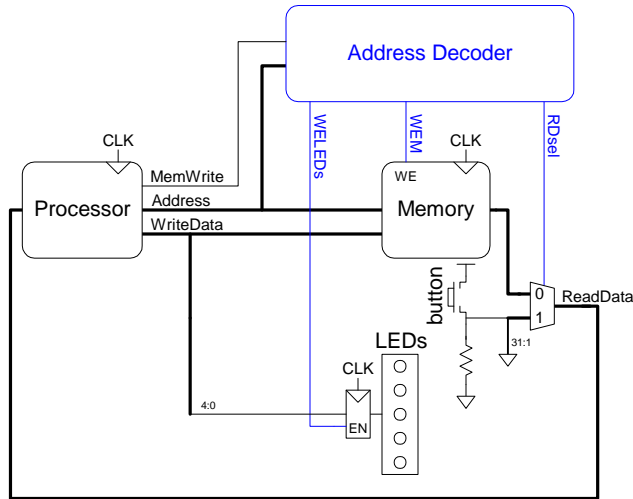

```
# MIPS code for Exercise 8.28
# The LEDs are mapped to the 5 least significant bits at
# memory address 0xFFFFF14

      addi $t1, $0, 0x15    # the random pattern to display to the LEDs
Loop0: lw  $t0, 0xFF10($0)  # $t0 = button value
      beq  $t0, $0, Loop0   # if button is not pressed, keep checking
      sw   $t1, 0xFF14($0)  # if $t0 == 1, display pattern on LEDs
```

```

Loop1: lw    $t0, 0xFF10($0) # $t0 = button value
      bne   $t0, $0, Loop1  # if button is still pressed, loop
      sw    $0, 0xFF14($0)  # clear LEDs when button is not pressed
      j     Loop0           # check when button is pressed
    
```

(b)

(c) Address Decoder for Exercise 8.28

SystemVerilog

```
module addrdec(input logic [31:0] addr,
               input logic memwrite,
               output logic WELEDs, Mwrite,
               output logic rdselect);

    parameter B = 16'hFF10; // push button
    parameter LEDs = 16'hFF14; // LEDs

    logic [15:0] addressbits;

    assign addressbits = addr[15:0];

    always_comb
        if (addr[31:16] == 16'hFFFF) begin
            // writedata control
            if (memwrite)
                if (addressbits == LEDs)
                    {WELEDs, Mwrite, rdselect} = 3'b100;
                else
                    {WELEDs, Mwrite, rdselect} = 3'b010;

            // readdata control
        else
            if ( addressbits == B )
                {WELEDs, Mwrite, rdselect} = 3'b001;
            else
                {WELEDs, Mwrite, rdselect} = 3'b000;
        end
    else
        {WELEDs, Mwrite, rdselect} =
            {1'b0, memwrite, 1'b0};

endmodule
```

VHDL

```
library IEEE; use IEEE.STD_LOGIC_1164.all;
entity addrdec is -- address decoder
    port(addr:          in STD_LOGIC_VECTOR(31 downto 0);
          memwrite:     in STD_LOGIC;
          WELEDs, Mwrite, rdselect: out STD_LOGIC);
end;

architecture struct of addrdec is
begin
    process(all) begin
        if (addr(31 downto 16) = X"FFFF") then

            WELights <= '0'; Mwrite <= memwrite; rdselect <= '0';
        end if;
    end process;
end;
```

Question 8.1

Caches are categorized based on the number of blocks (B) in a set. In a direct mapped cache, each set contains exactly one block, so the cache has $S = B$ sets. Thus a particular main memory address maps to a unique block in the cache. In an N-way set associative cache, each set contains N blocks. The address still maps to a unique set, with $S = B / N$ sets. But the data from that address can go in any of the N blocks in the set. A fully associative cache has only $S = 1$ set. Data can go in any of the B blocks in the set. Hence, a fully associative cache is another name for a B-way set associative cache.

A **direct mapped cache** performs better than the other two when the data access pattern is to sequential cache blocks in memory with a repeat length one greater than the number of blocks in the cache.

An **N -way set-associative cache** performs better than the other two when N sequential block accesses map to the same set in the set-associative *and* direct-mapped caches. The last set has $N+1$ blocks that map to it. This access pattern then repeats.

In the direct-mapped cache, the accesses to the same set conflict, causing a 100% miss rate. But in the set-associative cache all accesses (except the last one) don't conflict. Because the number of block accesses in the repeated pattern is one more than the number of blocks in the cache, the fully associative cache also has a 100% miss rate.

A **fully associative cache** performs better than the other two when the direct-mapped and set-associative accesses conflict and the fully associative accesses don't. Thus, the repeated pattern must access at most B blocks that map to conflicting sets in the direct and set-associative caches.

Question 8.2

Virtual memory systems use a hard disk to provide an illusion of more capacity than actually exists in the main (physical) memory. The main memory can be viewed as a cache for the most commonly used pages from the hard disk. Pages in virtual memory may or may not be resident in physical memory. The processor detects which pages are in virtual memory by reading the page table, that tells where a page is resident in physical memory or that it is resident on the hard disk only. The page table is usually so large that it is resident in physical memory. Thus, each data access requires potentially two main memory accesses instead of one. A translation lookaside buffer (TLB) holds a subset of the most recently accessed TLB entries to speedup the translation from virtual to physical addresses.

Question 8.3

The advantages of using a virtual memory system are the illusion of a larger memory without the expense of expanding the physical memory, easy relocation of programs and data, and protection between concurrently running processes.

The disadvantages are a more complex memory system and the sacrifice of some physical and possibly virtual memory to store the page table.

Question 8.4

If the virtual page size is large, a single cache miss could have a large miss penalty. However, if the application has a large amount of spatial locality, that

page will likely be accessed again, thus amortizing the penalty over many accesses. On the other hand, if the virtual page size is small, cache accesses might require frequent accesses to the hard disk.

Question 8.5

No, addresses used for memory-mapped I/O may not be cached. Otherwise, repeated reads to the I/O device would read the old (cached) value. Likewise, repeated writes would write to the cache instead of the I/O device.
